In order to calculate losses at high inductions, it is probably not feasible to obtain loops accurately at much higher values ballistically. We believe, however, that the percentage losses will not increase very much beyond those given for $B_m = 17$. Let us refer to Fig. 3 showing the data for $B_m = 17$. At higher values of B the ascending and descending branches apparently nearly coincide. It is possible that a displaced loop at very high B would have little or no area. This should certainly be true if the loop limits were entirely above the saturation point. At very high B_m values then the percentage curves might even decrease. There seems to be a tendency in this direction, at least for the B and C samples. We believe therefore that no serious errors would be introduced by using the K curves for $B = 17$ kilogausses (98.3 lines per square inch) for all higher inductions.

For other kinds of material the only other factor necessary to consider for approximate results is the specific normal hysteresis loss per cycle at the given B_m or C of formula (2).

Of course, when the designer comes to apply these results to a specific problem there will be a number of uncertain factors such as amplitude, percentage of tooth pulsation at various parts of the tooth, flux density of the teeth, etc. Moreover, these results have been put into usable form only for a sine wave field form and would have to be recalculated in a different way for other field forms. In addition to tooth pulsation losses, it is believed that the results may be used for the calculation of pole face losses as well by proper manipulation.

Finally these data should be applicable where the whole flux pulsates due to high-frequency reluctance variations in the air gap.

Future Work

In order to apply these data, a more accurate knowledge of the magnitude, distribution and depth of penetration of these tooth pulsation seems essential. An estimate of the magnitude of these pulsations is made very difficult due to the damping action of the eddy and circulating currents in the iron and copper.

In conclusion I wish to acknowledge the assistance of Mr. G. H. Keulegan who did most of the experimental work.

Skin Effect in Large Stranded Conductors at Low Frequencies

BY W. I. MIDDLETON and E. W. DAVIS

Both of the Simplex Wire & Cable Co.

THE resistance of metallic conductors is higher for alternating currents than for direct currents, due to the so-called "skin-effect." With alternating currents, the distribution is not uniform throughout the cross-section, there being a tendency for the current to concentrate towards the outside of the conductor, thus causing an increase of resistance and consequent increase of power loss.

Fig. 1 shows the power loss per 1000 feet in a 1,000,000-cir. mil cable; curve A gives the loss when the cable

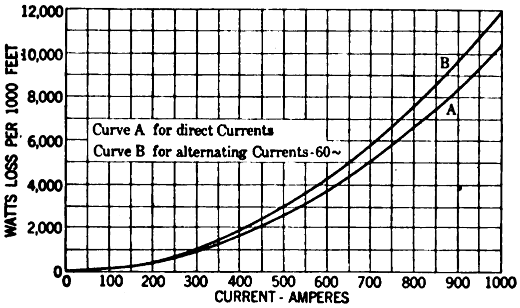

FIG. 1—WATTS LOSS PER 1000 FT.

Copper wire, 1,000,000 cir. mils

Resistance: D-c.—0.01034 ohms per 1000 ft.

A-c.—0.01186 " " " "

is carrying direct currents; curve B gives the loss when the cable is carrying 60-cycle alternating currents. The larger losses shown by the curve B are caused by the higher resistance of the cable to alternating currents than to direct currents.

The current density throughout the cross-section of any large size conductor carrying alternating currents is similar to those shown by the curves in Fig. 2. The density at the outside of the conductor is assumed as unity.

The increased demand for large size conductors carrying heavy alternating currents has aroused the interest of engineers to the importance and magnitude of the increase of resistance due to skin effect.

Much experimental work has been done to determine the skin effect in small conductors at radio and telephonic frequencies, and the results are of inestimable value to the radio and telephone engineer. Very little experimental work has been done at the low frequencies of 25 and 60 cycles, although many theoretical and approximate formulas are available.

There are three common formulas for skin effect which we shall designate as A, B and C respectively.

Formula A is found in the Appendix to Sir Wm. Thomson's Inaugural Address to the Institution of Electrical Engineers in 1889.

σ = specific resistance, c. g. s. units
= 1610 for copper

a = radius of wire

$R(S) = \dfrac{\sigma l}{\pi a^2}$ = resistance of any length l of a wire with steady currents

$R(N)$ = effective ohmic resistance of the same length l with alternate current of N periods per second

$$q = \left(2\pi\sqrt{\frac{2N}{\sigma}}\right) r$$

where $r = a$

$$\frac{R(N)}{R(S)} = \frac{1}{2}\, q \times \frac{ber.q\ bei'.q - bei.q\ ber'.q}{(ber'q)^2 + (bei'q)^2}$$

By ber and bei, denote two functions defined as follows:

$$ber.q = 1 - \frac{q^4}{2^2\,4^2} + \frac{q^8}{2^2\,4^2\,6^2\,8^2} \ldots \text{etc.}$$

$$bei.q = \frac{q^2}{2^2} - \frac{q^6}{2^2\,4^2\,6^2} + \frac{q^{10}}{2^2\,4^2\,6^2\,7^2\,10^2} \ldots\ldots \text{etc.}$$

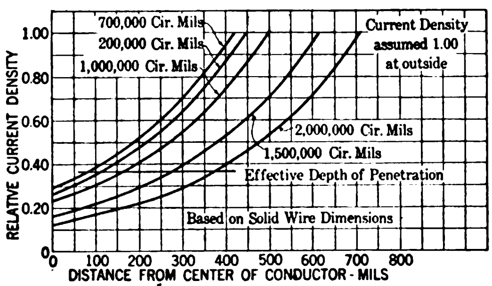

FIG. 2

The accents denote differential coefficients.

$$ber'.q = -\frac{4q^3}{2^2\,4^2} + \frac{8q^7}{2^2\,4^2\,6^2\,8^2} \ldots \text{etc.}$$

$$bei'.q = \frac{2q}{2^2} - \frac{6q^5}{2^2\,4^2\,6^2} + \frac{10q^9}{2^2\,4^2\,6^2\,8^2\,10^2} \ldots \text{etc.}$$

The following table of numerical results has been calculated using the above formula:

TABLE I

Formula B. In "Absolute Measurements in Electricity and Mangetism" by A. Gray, Vol. II, Part I, the following statement is made regarding effective resistance:

"The effective resistance is the same as the resistance which a surface stratum of the conductor of thickness

$$\frac{1}{a} = \frac{1}{\sqrt{2\,\pi\,\mu\,K\,\eta}}$$

would offer to a steady current."

$\frac{1}{a}$ = thickness in centimeters

μ = permeability of conductor material

η = frequency — cycles per second

K = constant depending on conductor material

= 0.00384 for copper

By this formula, the thickness of the surface stratum of a copper conductor carrying 25-cycle current is 1.29 cm. or 508 mils; for 60-cycle current it is 0.835 cm. or 329 mils. This "thickness of the surface stratum" may be referred to as the "effective depth of penetration" of the current

Formula C is published by D. B. Rushmore in the TRANSACTIONS of the A. I. E. E., 1912, Vol. XXXI, Part I, page 262.

C_s = skin effect ratio

d = diameter of conductor—inches

f = frequency

R = resistance to direct currents

R_1 = resistance to alternating currents

$R_1 = C_s R$

$$C_s = \frac{1 + \sqrt{1 + \left(\frac{K}{\sigma}\right)^2}}{2}$$

$$\left(\frac{K}{6}\right) = 0.0105\,d^2 f \text{ for copper}$$

Table II shows the skin effect factors for 1,000,000-cir. mil and 2,000,000-cir. mil copper cables as calculated by the three formulas given.

TABLE II

Skin effect factors—1,000,000-cir. mil and 2,000,000-cir. mil cables at 60 cycles

Size cir. mils	Outside Dia. inches	Formula A	Formula B	Formula C
1,000,000	1.157	1.176	1.24	1.155
2,000,000	1.625	1.588	1.545	1.471

In large size conductors which are to be used for alternating currents, it is common practise to substitute a rope or fiber core, for the center strands, which have a very low current density. With the increased demand for such conductors, the lack of standardization in the size of the rope used becomes very apparent. It is not uncommon to have specifications for conductors of the same cross-section to be operated on the same type of systems, calling for rope cores more than 50 per cent different in diameter. Specifications written a few years back call for rope cores 18/32 in. to 28/32 in. for various sizes of conductors, while specifications written more recently require cores of 14/32 in. to 41/32 in. diameter. All of these specifications are in common use.

The wide variations in specifications and the apparent lack of experimental data led the authors to conduct the tests described below.

The size of rope core used for any conductor is dependent upon the skin effect ratio of that conductor and should be of such size as to make the effective resistance of the conductor for the working frequency sensibly the same as its resistance to direct currents.

Formulas A, B, C are theoretical or approximate formulas that may be used for skin effect calculation in the design of a rope-core cable. Formula A is a theoretical mathematical formula, the theory of which

is based upon the assumption of solid conductors. It is too complicated and the numerical substitutions are too tedious to be of great value to the average engineer. There are many simplified and approximate formulas which are claimed to be modifications of Thomson's formulas, and which may be found in many electrical text-books and handbooks. The use of these formulas, however, gives widely varying results when applied to stranded conductors. Formula *C* is an approximate formula, but it checks the theoretical formula better than most such formulas.

Formula *B* appeals to the authors as the simplest of the three as it gives a certain definite effective penetration of alternating currents from the surface of a conductor. For copper conductors, this penetration

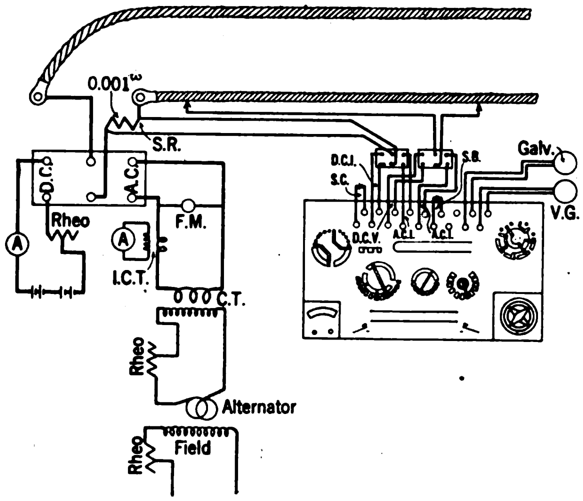

FIG. 3

A	= ammeter	*A. C. V.*	= a-c. volts
F. M.	= frequency meter	*C. T.*	= current transformer
S. C.	= standard cell	*S. B.*	= 8-volt storage battery
D. C. I.	= d-c. current	*V. G.*	= vibrating galvanometer
D. C. V.	= d-c. volts	*I. C. T.*	= instrument current transformer
A. C. I.	= a-c. current	*S. R.*	= standard resistance

depends only upon the frequency. The numerical value of the penetration is easily remembered, being 329 mils for 60-cycle current and 508 mils for 25-cycle current.

The following tests were made to obtain experimental data concerning the effective resistance of large-size stranded conductors to alternating currents of the low frequencies of 25 and 60 cycles. Particular attention was paid to the calculated effective depths of penetration of the current, in order to determine how far and with what modifications formula *B* can be applied to stranded conductors.

The skin effect was determined by measuring the current in the cables, the voltage drop across a known length of cable, and the phase angle between this current and voltage. A Drysdale alternating and continuous-current potentiometer was used. The current was determined by the use of a current transformer, and checked by voltage measurements across a standard 0.001-ohm resistance.

A coil attached to the cable would have a voltage induced between its terminals in phase with the current in the cable. The phase angle between this voltage and the voltage across a known length of cable is the phase angle between the current and voltage of the cable. This method was used to determine the phase angles between currents and voltages in these tests.

Current for the direct-current tests was supplied by a set of storage batteries; the current for the 25-cycle tests was supplied by a 25-kv-a. single-phase generator; the current for the 60-cycle tests was supplied by a commercial city circuit.

The cable samples were looped around the floor. Tests showed that the size of the loop had little or no effect upon the effective resistance. A diagram of the connections is shown in Fig. 3.

The cable samples tested were usually fifty feet in length, potentiometer measurements being made between two potential points fifteen feet apart.

Tests at 25 and 60 cycles were made on 700,000-cir. mil, 800,000-cir. mil, 1,000,000-cir. mil 1,500,000-cir. mil, and 2,000,000-cir. mil cables, dimensions of which are shown in Table III.

Average penetration from above results—504 mils
Calculated penetration from Gray's formula—508 mils

Table IV gives the results of the tests made at 25 cycles. Various current values were used for each

conductor in order to determine if there was any effect of current density upon the effective resistance.

In calculating the effective current penetration, the pitch diameter of the conductor, rather than the outside diameter, is used. Tests made at 500 cycles for the specific purpose of checking Gray's formula as applied to stranded conductors, indicate that the current penetration should be calculated from the pitch diameter of the outer layer of strands. The results of the 500-cycle tests are shown later.

Average penetration from above results—329 mils
Calculated penetration from Gray's formula—329 mils

Table V gives the results of test made at 60 cycles. As in the case of the 25-cycle tests, different current densities have no effect upon the effective resistance. The largest deviation between the average effective current penetration for any size and that of 329 mils calculated by Gray's formula, is for 700,000 cir. mils, a deviation of 8.2 per cent. This large deviation is probably due to the slightly fluctuating frequency during these particular tests.

TABLE VI

In order to determine experimentally whether skin effect calculations, based on the pitch diameter of a stranded conductor, are correct, 500-cycle tests were made on four specially designed cables of the dimensions shown in Table VI. An attempt was made to have four cables of approximately the same diameter, the same copper circular mils, but laid up with widely different stranding. The result was four cables having very different pitch diameters.

At 500 cycles, skin effect is much more pronounced than at 25 cycles or 60 cycles, and therefore much more conclusive results would be expected. If the skin effect of a conductor were a function of the copper circular mils or the outside diameter, the ratio of resistances for these four cables should be approximately the same.

Average penetration from above results–112 mils
Calculated penetration from Gray's formula–113 mils

Table VII shows the results of the tests made at 500 cycles. A glance at the resistance ratios shows that they do not follow as a function of the outside diameter or of the circular mils. The effective current penetration, calculated from the pitch diameter, however, checks very closely with the theoretical value of 113 mils for 500 cycles, calculated by Gray's formula. This would indicate that for stranded conductors, skin effect calculations should be based on the pitch diameter of the outer layer of strands.

Fig. 4 shows a cross-section of the four special cables used for the 500-cycle tests. The shaded sections are called "useless copper," that is, the copper inside the effective depth of current penetration.

The seven-strand cable has considerably less useless copper than the other three, we believe because of its much smaller pitch diameter. The 61-strand cable has the largest pitch diameter and the largest amount of useless copper. This would indicate that for concentric stranding, the larger the size strand for any given circular mileage the less the skin effect.

Table VIII gives the stranding and dimensions of three extra flexible, rope-stranded, 2,000,000-cir. mil

cables. Tests were made on these cables in order to determine whether they followed the same formula for skin effect as the concentric stranded cables.

FIG. 4

Fig. 5 shows diagrammatically the method used to make measurements on these cables.

P-T is a direct-current potentiometer so wound that it is suitable for 60-cycle alternating currents. *M* is

TABLE VIII

Dimensions—Extra flexible 2,000,000 cir. mils

Stranding	Actual cir. mils	Outside dia.	Pitch dia.
37—(7 × 7-0335)	2,034,190	2.110	1.809
61—(7 × 7-0265)	2,098,280	2.146	1.907
127—(7-0485)	2,090,930	1.892	1.745

a mutual inductance, the primary of which is connected in series with the potentiometer as shown. The current in the inductance primary, and in the potentiometer circuits, are in phase; any potentiometer voltage

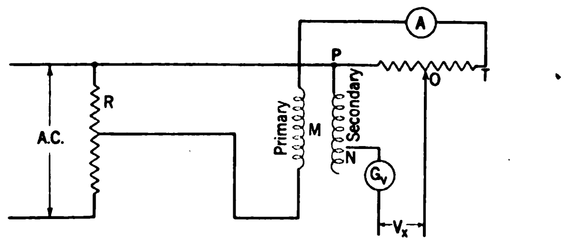

FIG. 5

A = ammeter
$P\ O\ T$ = d-c. potentiometer
M = mutual inductance
V_x = unknown voltage
G_v = vibration galvanometer
R = rheostat

PO, is in phase with this current; any induced voltage in the inductance secondary is 90 deg. out of phase with this current. By keeping the current through the inductance potentiometer circuit constant at rated current for the potentiometer, the voltage *PO*, is read directly, and the voltage *P Z* may be readily calculated.

$$V_{pz} = 2\pi f L \times I$$
f = frequency
I = potentiometer current
L = inductance

The total voltage $Z\,O = \sqrt{(V_{pz})^2 + (V_{po})^2}$

This method of measurement is much simpler to set up and operate than the a-c. potentiometer; it does not require any difficult phase-splitting and does not require any complicated or unusual apparatus.

The same measurements on the cables were made as when the Drysdale alternating- and continuous-current potentiometer was used, and the same methods used to calculate results.

Table IX shows the results at 25 cycles and Table X at 60 cycles.

Average penetration from above tests—338 mils
Average penetration from Gray's formula—329 mils

From these tests it is apparent that the skin effect of rope-stranded cables can be calculated to a fair degree of accuracy by assuming the same current penetration as for solid or concentric stranded conductor; and that the current penetration should be calculated from the pitch diameter of the outside layer of bunches of strands.

Conclusions

1. The effective resistance of a conductor to alternating current depends upon the amount of conducting material in a surface stratum of approximately 508 mils thickness for 25 cycles and approximately 329 mils for 60 cycles. The thickness of this "surface stratum" is referred to as the "effective depth of current penetration."

2. Effective depth of current penetration is the same for stranded conductors as for solid conductors. For stranded conductors, the depth should be calculated from the pitch diameter of the outer layer of strands.

3. Skin effect of *stranded* conductors is not a direct function of the total copper circular mils or of the outside diameter.

4. Skin effect in any conductor is independent of the current.

5. Current penetration varies as the square root of the current frequency.

6. The larger the size of strand used for any conductor, the less the skin effect and the less the amount of useless copper. For practical purposes, the size of strand should not be so large as to interfere with the flexibility of the cable.

The writers believe that the subject is of sufficient importance to warrant a very thorough investigation, that all experimental data available should be published, and that the matter should receive the attention of the Institute in its Standards.

The authors are indebted to the electrical engineering departments of Harvard University and Massachisetts Institute of Technology for the use of special apparatus and for suggestions in this work.

APPENDIX

Rope-Core Cables

Table XI shows the range of rope-core diameters in use at the present time for various sizes of conductors.

TABLE XI

Size Cond. cir. mils	Dia. Rope Core inches
2,000,000	28/32 to 41/32
1,750,000	25/32 to 39/32
1,500,000	22/32 to 34/32
1,250,000	18/32 to 27/32
1,000,000	15/32 to 19/32
800,000	11/32 to 16/32
700,000	9/32 to 14/32

The smaller the over-all diameter of a copper conductor, the less expensive the finished cable. Thus it is to the advantage of the purchaser when considering the first cost of an installation, to specify the lower limit diameters of rope cores. On the other hand, if the rope core is not sufficiently large, the cable will contain a considerable amount of copper which is not being effectively used.

Applying Gray's formula to stranded cables by calculating the effective depth of current penetration from the pitch diameter of the outer layer of strands, the ideal strand for any rope-core cable may be readily determined.

Let N = number of layers of strands

Z = effective depth of current penetration for the working frequency

d = diameter of ideal strand

$$d = \frac{Z}{N - 0.5}$$

d will be in the same units that are used to express the depth of penetration.

TABLE XII

Ideal strands for rope-core cables

Frequency	Layers of strands over rope core		
	3	4	5
25		145 mils	113 mils
60	131.5 mils	94 mils	

Table XII shows the ideal strands to be used for rope-core cables at frequencies of 25 and 60 cycles.

TABLE XIII

Dimensions of rope-core cables—25 cycles
Using ideal strand

Size cond.	Rope core diam.	Strand	Outside diameter	Actual cir. mils
1,250,000	0.140	98 —0.1135	1.27	1,250,000
1,500,000	0.320	117—0.1135	1.45	1,490,000
1,750,000	0.400	83—0.145	1.56	1,748,000
2,000,000	0.547	95—0.145	1.71	2,000,000

TABLE XIV

Dimensions of rope-core cables—60 cycles
Using ideal strand

Size cond.	Rope Core	Strand	Outside diam.	Actual cir. mils
700,000	0.225	80—0.094	0.98	706,000
800,000	0.324	91—0.094	1.08	803,000
1,000,000	0.504	113—0.094	1.26	998,000
1,250,000	0.665	73—0.1315	1.46	1,261,000
1,500,000	0.834	87—0.1315	1.62	1,505,000
1,750,000	1.041	101—0.1315	1.83	1,749,000
2,000,000	1.249	116—0.1315	2.04	2,010,000

Tables XIII and XIV show the dimensions of ropes, outside diameters, and actual cir. mils for rope-core cables using the ideal strands listed in Table XII. In actual practise these cables should be modified so that commercial sizes of rope and ordinary strands can be used.

Tables XV and XVI show dimensions of rope-core cables, using B. & S. sizes for strands. The diameters of cores are those found for commercial ropes. The method of stranding (*i. e.*, using B. & S. sizes) is in accordance with the latest N. E. Code rulings.

TABLE XV

Rope-core cables for 25 cycles—Using B & S sizes for strands

Nominal cir. mils	Rope core		Stranding	Actual cir. mils	Per Cent deviation from nominal cir. mils	Outside diam.
	Theoretical	Actual				
1,500,000	19/64 +	10/32	72 strds #7	1,500,000	0	1.46
1,750,000	27/64 +	14/32	84 " #7	1,750,000	0	1.59
2,000,000	20/32 +	20/32	98 " #7	2,040,000	+2	1.78

TABLE XVI

Rope-core cable for 60 cycles—Using B & S sizes for strands

AMERICAN ELECTRICAL MACHINERY FOR AUSTRALIA

The State Electricity Commission of Victoria for some months past has been engaged in arranging for the execution of the various portions of the State electricity project. Trade Commissioner A. W. Ferrin states in *Commerce Reports* that tenders from the United States have recently closed for that portion of the electrical installation comprised under the general heading of "transformers and switch gear." This includes the whole of the apparatus which transforms the electric energy from the voltage of generation at Morwell up to the voltage of transmission; also the switch gear and the electrical mechanism for operating the apparatus and all the control gear. It also includes the step-down transformers, synchronous condensers and switch gear of the Newport terminal station, as well as apparatus for a number of metropolitan substations. The tender for the whole apparatus by an American company was much less than the lowest possible combination of English tenders. The terms of delivery offered by this company was also more satisfactory than that offered by any other tender, and the State Electricity Commission therefore recommended to the Government that the tender be accepted. The commission has also recommended the acceptance of an American company's tender for the supply of conductors for the main transmission line from Morwell to Newport. The line will comprise six separate wires, making the total length of the conductors about 700 miles. The alternative materials open for consideration were copper and aluminum-coated steel. The tenders received showed a heavy advantage in favor of steel, which has the further advantage of greater strength than copper, thus permitting of the employment of longer spans and therefore of fewer steel towers, insulators, etc. It is estimated that by the employment of steel-aluminum instead of copper conductors a total saving upon the whole outlay on the transmission line of about £100,000 will be effected.

NEW ELECTRIC PLANT AT NANKING

Owing to the inability of the existing electric plant at Nanking to furnish sufficient current to meet the needs of the city and its suburbs, a new plant has recently been added. The plant complete, exclusive of the site, cost the equivalent of $125,000 American currency. The generator is an American made turbo-generator producing a 2300-volt, three-phase and 60-cycle current with direct-connected exciter. The boiler-feed pump and supply pumps are of American manufacture. The feed-water heater is also American, as is the 4-inch by 5-inch vertical steam engine used for the stoker drive. The building for the new plant was erected by the Nanking Electric Light Co. under the supervision and according to the plan of an American-educated Chinese engineer. The installing of the machinery was done by an American engineering firm.

JOURNAL
OF THE
American Institute
of Electrical
Engineers

PUBLISHED MONTHLY BY THE A. I. E. E.
33 West 39th Street, New York
Under the Direction of the Publication Committee

Subscription. $10.00 per year to United States, Mexico, Cuba, Porto Rico, Hawaii and the Philippines; $11.00 to Canada and $12.00 to all other countries. Single copies $1.00. Volumes begin with the January issue.

Changes of advertising copy should reach this office by the 15th of the month for the issue of the following month.

A. I. E. E. MEETINGS

CHANGE OF POLICY

The following resolutions relating to Institute meetings were adopted at a meeting of the Board of Directors held May 20, 1921, upon recommendation of the Committee on Coordination of Institute Activities:

RESOLVED: (1) To place all regular monthly meetings of the Institute and Sections throughout the country on the same basis; that is to make them all Section meetings.

(2) To continue the three general meeting of the Institute each year, namely, the Annual, Pacific Coast and Midwinter Conventions, and the annual business meeting in May, with such other additional meetings as may be authorized from time to time by the Board of Directors.

(3) To hold the Directors' meetings in New York City, excepting when the Board, for special reasons, decides to meet elsewhere.

RESOLVED further: That the policy outlined above be adopted with the understanding that the regional vice-presidents, in accordance with the recommendations of the Development Committee, will visit the Sections in their respective territories and otherwise assist in coordinating their activities; also that the Meetings and Papers Committee at headquarters will cooperate with the respective Sections and render such aid as may be feasible in developing desirable programs for Section meetings.

At a meeting of the Directors held August 16, 1921, the following resolution was adopted:

RESOLVED: That, beginning with the calendar year 1922, in addition to the annual meeting there shall be four general meetings of the Institute, including the Annual Convention.

The above resolutions have been referred to the Meetings and Papers Committee and the Committee on Coordination of Institute Activities for guidance in forming plans for coming meetings; and it is expected that these committees will formulate detailed recommendations which will receive consideration by the Directors in October.

A. I. E. E. NOVEMBER MEETING

JOINT SESSION WITH THE SOCIETY OF NAVAL ARCHITECTS AND MARINE ENGINEERS

The 372d meeting of the Institute will be held in the Engineering Societies Building on Thursday, November 17, 1921. The meeting will consist of an afternoon and an evening session.

The afternoon session will be a joint session with the Society of Naval Architects and Marine Engineers, forming a part of the annual meeting of that society. Two papers will be presented at this session as follows:

Electric Auxiliaries, by E. D. Dickinson, Marine department of the General Electric Co.

Electric Propulsion, by W. E. Thau, Commerical Engineer of the Westinghouse Electric and Mfg. Co.

The evening session will be devoted to a lecture on *World Communication*, by Alfred N. Goldsmith, Professor of Electrical Engineering, City College of New York.

A. I. E. E. DIRECTORS MEETING

AUGUST 16, 1921

The first meeting of the Board of Directors of the American Institute of Electrical Engineers for the administrative year beginning August 1, 1921, was held at Institute headquarters, New York, on Tuesday, August 16.

There were present: President William McClellan, Philadelphia; Past Presidents, A. W. Berresford, Milwaukee and Calvert Townley, New York; Vice-Presidents N. W. Storer, Pittsburgh, F. W. Springer, Minneapolis, W. A. Hall, Boston, J. C. Parker, Ann Arbor, Mich., W. A. Del Mar, Yonkers, N. Y.; Managers, G. Faccioli, Pittsfield, Mass., Frank D. Newbury and A. G. Pierce, Pittsburgh, E. B. Craft and Harlan A. Pratt, New York, R. B. Williamson, Milwaukee; Treasurer, George A. Hamilton, Elizabeth, N. J.; Secretary, F. L. Hutchinson, New York.

Approval by the Finance Committee of monthly bills amounting to $16,746.40 was ratified.

A report was presented of a meeting of the Board of Examiners held August 8, 1921. Upon the recommendation of the Board of Examiners, the following action was taken upon pending applications: 34 Students were ordered enrolled; 106 applicants were elected to the grade of Associate; 20 applicants were elected to the grade of Member; 15 applicants were transferred to the grade of Member; 5 applicants were transferred to the grade of Fellow.

President McClellan announced the appointments of committees for the administrative year beginning August 1, 1921. (These committees are listed elsewhere in this issue.)

In accordance with the by-laws of the Edison Medal Committee, the Board confirmed the appointment by the President of Messrs. B. A. Behrend, John H. Finney and Charles S. Ruffner to the Edison Medal Committee for a term of five years, and elected from its own membership Messrs. A. W. Berresford, L. F. Morehouse and R. B. Williamson, to serve upon the Edison Medal Committee for a term of two years.

Local Honorary Secretaries Guido Semenza, for Italy and Charles leMaistre, for England, were reappointed for a term of two years ending July 31, 1923.

The following representatives of the Institute upon the American Engineering Council, of the Federated American Engineering Societies, whose terms expire December 31, 1921, were reappointed for a term of two years ending December 31, 1923: Messrs. H. W. Buck, W. A. Layman, Wm. McClellan, L. F. Morehouse, L. T. Robinson, C. S. Ruffner.

President McClellan made the recommendation that meetings of the Board of Directors be held bi-monthly in future, and in New York City in accordance with the action taken by the Board at its May meeting; the Executive Committee to take

action on all matters that need attention between meetings of the Board. The following resolution was adopted:

RESOLVED, that starting with October 1921, the regular meetings of the Board of Directors shall be held in New York City, at approximate intervals of two months, and arranged so as not to prevent the attendance of members of the Board at meetings of the Institute.

The following minute was adopted as a memorial to Francis Bacon Crocker, Past President of the Institute:

With Francis Bacon Crocker, whose death occurred on July 9, 1921, there passed one of the ablest electrical engineers of the world. Interested in the art and science of electrical engineering from early childhood, he served the profession as few men have been permitted to serve. As a pioneer designer of commercially successful motors, as a founder and director of the School of Electrical Engineering at Columbia University and in a similar capacity with the Crocker-Wheeler Company, as an advocate of world standardization in the electrical field—in all the numerous activities with which he was connected, Dr. Crocker's genius is indelibly recorded.

It is, therefore, with a sense of extraordinary loss to the engineering profession that the Board of Directors of the American Institute of Electrical Engineers records the death of one who served as President for the year 1897-1898 and as chairman and member of many committees, decrees that this minute be entered in the Institute records as an expression of its appreciation of his personality, career and attainments.

In addition to these actions other matters relating to important activities and the general policy of the Institute were discussed; reference to these matters may be found in this and future issues of the JOURNAL under suitable headings.

AMERICAN ENGINEERING COUNCIL

MEETING OF EXECUTIVE BOARD

Washington, September 30

The Executive Board of American Engineering Council of the Federated American Engineering Societies will meet in Washington, D. C., on September 30. The most important business of the meeting will be the election of a president to succeed Herbert Hoover, who resigned after becoming Secretary of Commerce. Nominations to fill this office were ordered at the last Board meeting, so that they could be reported at the September meeting. Other matters bearing on the management of Council, its membership, and the work of its committees will be taken care of at this meeting. The Board will give special attention to the plans for the Engineering Assembly (see below), the extension of employment service, and the question of licensing and registration of engineers.

ENGINEERING ASSEMBLY

An Engineering Assembly, authorized by a special vote of the Executive Board at the Philadelphia meeting, will be held in conjunction with the annual meeting of American Engineering Council, next January. It is planned to make the assembly a three-day session, one day to be given to special meetings of the executive boards of member organizations and committees of the American Engineering Council, one day to the sessions of the American Engineering Council, and at least one day to the discussion of some special topic such as elimination of waste, licensing of engineers. the national department of public works or some other subject of equal importance to the engineering profession.

An Engineering Assembly Committee has been appointed with A. P. Davis of Washington, Chairman, and with the following members: Philip N. Moore of St. Louis, L. P. Alford of New York City, John C. Hoyt of Washington, and F. A. Vaughn of Milwaukee. This committee will work out detailed plans for the assembly.

NEW EDITION OF N. E. L. A. REPORTS

The demand for copies of the reports of the Prime Movers Committee and of the Overhead Systems Committee of the National Electric Light Association exhausted the original edition and both reports have been reprinted in full.

The report of the Prime Movers Committee covers, turbines, condensing equipment, boilers and auxiliaries, stokers, economizers, power station auxiliaries, coal and ash handling, piping, boiler and turbine room instruments, buildings and foundations and power station sites, oil and gas engines, and various fuels. It contains 360 pp. 8 x 11 in., illustrated, $3.50 to members, $7.00 to non-members.

The report of the Overhead Systems Committee includes: transmission line construction, insulator maintenance and research, maintenance of live transmission lines, line construction materials, revision of wood pole specifications, use of concrete poles, lightning arrester practise, operation and maintenance of transformers, etc. It contains 204 pp. 8 x 11 in. illustrated, $2.00 to members, $4.00 to non-members.

E. M. F. ELECTRICAL YEAR BOOK

A new electrical reference book has just been published by the Electrical Trade Publishing Co., of Chicago, under the title of E. M. F. Electrical Year Book, which promises to make a very useful annual reference book of current information for the electrical industry. It comprises three leading features: Compilations of facts and figures about each branch of the industry, definitions of electrical and allied terms, and a classification of products made and used by the industry with listings of their producers. All topics are entered alphabetically, the entire text being arranged as in an encyclopedia or dictionary so that it is very easy to find any item desired.

All the editorial work on the book was done under the general direction of Frank H. Bernhard, who has been on the editorial staffs of various electrical publications. Most of the technical topics were prepared by a staff of some thirty contributing editors, including college professors, electrical engineers and other specialists in their respective lines.

The book contains about 1000 pages, 9 by 12 in., and is priced at $10.

PERSONAL MENTION

CHARLES F. SCOTT has been elected president of the Society for the Promotion of Engineering Education.

V. A. ZEHR, consulting engineer of Pekin, Ill., sailed August 4th for Europe to investigate a construction work near Prague, Bohemia.

A. C. CORNELL has become manager of the Denver Supply Distributing House of the Western Electric Company. He has been sales manager of the company in Denver.

A. TELFORD SMITH, formerly with the Winnipeg Electric Railway Company, Winnipeg, Man., is now located with the Sao Paulo Electric Company, Ltd., Sao Paulo, Brazil.

J. M. WAUCHOPE has accepted appointment as superintendent of the Walla Walla River Plant of the Pacific Power & Light Company, at Milton, Ore.

A. T. RUSTAD, formerly of the Cutler-Hammer Mfg. Company, Milwaukee, Wis., is now located as inspector with Murrie & Company, construction engineers, New York City.

WARD B. KINDY has left the Iowa State College, where he was instructor in the Electrical Engineering Department, to take up the same work in Leland Stanford Jr. University.

ROBERT LINDSAY, who has been vice-president and general manager of the Cleveland Electric Illuminating Company, was recently elected president of the company.

H. R. Eilertsen has left the Cutler-Hammer Mfg. Co., where he was employed as service engineer, and is located with R. Hoe & Co., New York City.

Arthur W. Swisher, who was a junior engineer with the General Electric Company, has taken a position with The Falls Equipment Company, Niagara Falls, N. Y.

Robert N. Nielsen has left Lockwood, Greene & Co., Chicago, and is at present with the F. E. Newbery Electric Company, Chicago.

C. A. Malone, formerly of the California-Oregon Power Company, has become assistant superintendent of The Hawaiian Electric Co., Ltd., Honolulu, Hawaii.

Fred E. Dace has left the Holt Mfg. Company, Peoria, Ill., to accept a position as instructor in electricity and mathematics at Bradley Polytechnic Institute, Peoria.

Carlyle D. Bidwell, formerly superintendent of construction with the J. I. Case Plow Work Company of Racine, Wis., is now located with the West Pullman Works of the International Harvester Company, Chicago, as plant engineer.

W. H. R. Burrows has severed his connections with the Wabi Iron Works, New Liskeard, Ont., Can., where he was general manager, to become general manager of the Canada Electric Castings Co., Ltd., Orillia, Can.

H. A. Maxfield has left the Westinghouse Electric & Mfg. Co., where he was employed in the research laboratory, and is working in the electrical engineering laboratory of the Worcester Polytechnic Institute, Worcester, Mass.

Wm. C. Murrell has recently resigned his instructorship at Cornell University, and has taken a position in the Distribution Department of the Public Service Electric Company in Newark, N. J.

John W. Carrothers has accepted a position as voltage operator with the Kansas City Power & Light Company. He was formerly employed in the office of Hans von Unwerth, consulting engineer, of Kansas City.

John P. Kobrock, until recently with the Central Union Telephone Company, Chicago, as general outside plant engineer, is now located with the Ohio Bell Telephone Company, in Cleveland.

Philip S. Biegler, associate editor of *Electrical World*, has resigned from this position to become associate professor of Electrical Engineering at the State College of Washington, Pullman, Wash.

T. L. Holmes, of the Western Electric Company, has been appointed manager of the Boston Telephone Distributing House of that company. He has been with the company since 1900, his last office being in Denver, Col.

H. H. Argabrite, until recently stores manager of the Western Electric Company in Denver, Col., has been appointed manager of the Denver Telephone Distributing House of that company.

J. A. Woidill, Jr., formerly electrical chief draftsman of Hog Island Shipyard, has recently become superintendent of the Atlantic County Electric Company and Enterprise Gas Company, Egg Harbor City, N. J.

William McClellan, President of the American Institute of Electrical Engineers, has recently been appointed, by Governor Sproul, a member of the Pennsylvania State Board for Licensing Engineers, under the law passed at the last session of the Pennsylvania Legislature.

Carl T. Mack has severed his connections with Henry L. Doherty and Company of New York, with whom he was engaged in patent research work in Washington, D. C., and is now employed by the patent law firm of Prentiss, Stone and Boyden, of Washington.

Clarence F. Backstrand is now associated with Howard F. Ross in the Riverside Electric Company, engineers and electrical contractors, Riverside, Cal. Mr. Backstrand was until recently assistant district manager of the Holton Power Company, El Centro, Cal.

R. A. Lundquist, of the U. S. Department of Commerce, has been appointed head of the Electrical Machinery Division in the Bureau of Foreign and Domestic Commerce, one of the new industrial divisions made possible by Congress through the export industries act. The government plans to secure the services of experts in these departments to specialize in the important export products.

Pedro Diaz, who for several years was at the head of the Foreign Department of the Western Machinery Company, of Los Angeles, Cal., has resigned his position in order to establish himself in the City of Mexico as manufacturers' representative. Mr. Diaz has been appointed exclusive agent in the Republic of Mexico for the Western Machinery Company and the Layne & Bowler Corporation, both of Los Angeles.

Paolo Tuccimei, of the National Association of Italian Engineers, has been appointed by that organization as "Official Correspondent of the National Association of Italian Engineers for the States of North America." This appointment follows Mr. Tuccimei's recent trip to the United States, during which he visited American technical societies, and established friendly and cordial relations with them on behalf of the Italian association. Mr. Tuccimei has since communicated with the American societies, and with his position as correspondent officially recognized will be able to do much towards maintaining friendly relations, and providing for exchange of ideas and programs between the organizations.

OBITUARY

Earl Edwin Sayre of Schenectady, N. Y., was accidentally killed with his wife in a motorcycle accident at Oneonta, N. Y., on July 8, 1921. Mr. Sayre, who recently joined the Institute, was born at Durand, Mich., in 1895. He received his technical education at the Michigan Agricultural College, from which he was graduated in 1918. In May 1919 he entered the employ of the testing department of the General Electric Company at Schenectady, remaining there until his death. During the World War he had been in active service overseas as Lieutenant in the Wireless Division of the Signal Corps.

William Wilson Lighthipe, of Brooklyn, N. Y., died August 7, 1921, in the Long Island Hospital. He had been ill for some time. Mr. Lighthipe was one of the foremost engineers of the Otis Elevator Company, and was known throughout the country as an expert on elevators. He started with the Sprague Elevator Company in 1898, upon his graduation from Columbia University, and in 1900 became general superintendent. In 1901 he was appointed assistant superintendent of the Otis Elevator Company, but a year later became associated with the Marine Engine & Machine Company, New York. Re-

turning in 1905 to the Otis Elevator Company, he remained there in various capacities until his death, at which time he was manager of the special sales division of the company. He was born in Vincentown, N. J., in 1876. An Associate of the INSTITUTE, Mr. Lighthipe also belonged to the American Society of Mechanical Engineers, the Sons of the American Revolution, and the American Canoe Club.

ROBERT TEN EYCK LOZIER, a Fellow of the Institute, died of pneumonia at the Post-Graduate Hospital, New York, August 21, 1921. Mr. Lozier had been active in the pioneer work of developing electrical power, having been associated with many of the leading electrical engineers at a time when the technical schools and colleges did not have established courses in electrical engineering. He was born in South Norwalk, Conn., in 1868, and entered the office of Thomas A. Edison at the age of fourteen. This practical work, together with mathematical studies, made up his technical training. Until 1895 he was associated with various electrical concerns, among them the Sprague Electric Motor and Dynamo Company, the Edison General Electric and the General Electric Companies. In 1895 he started into business as a member of Warren & Lozier, engineers, but the next year became associated with the Bullock Electric Company, remaining there for eight years. After that time his work was largely that of consulting engineer, in New York City.

During the war Mr. Lozier devoted considerable time to hydroplane construction at the League Island Navy Yard, Philadelphia. For a short time thereafter he was connected with the Standard Underground Cable Company, but early in 1920 resumed his practise as industrial consultant. At the time of his death he had offices in New York and Chicago.

Mr. Lozier had been a manager of the Institute, 1902-4, and had served on various committees. He was also a life member and past-president of the New York Electrical Society, and a member of the Engineers Club.

ENGINEERING SOCIETIES LIBRARY

The library is a cooperative activity of the American Institute of Electrical Engineers, the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers and the American Society of Mechanical Engineers. It is administered for these Founder Societies by the United Engineering Society, as a public reference library of engineering and the allied sciences. It contains 150,000 volumes and pamphlets and receives currently most of the important periodicals in its field. It is housed in the Engineering Societies Building, 29 West Thirty-ninth St., New York.

In order to place the resources of the Library at the disposal of those unable to visit it in person, the Library is prepared to furnish lists of references to engineering subjects, copies or translations of articles, and similar assistance. Charges sufficient to cover the cost of this work are made.

The Director of the Library will gladly give information concerning charges for the various kinds of service to those interested. In asking for information, letters should be made as definite as possible, so that the investigator may understand clearly what is desired.

The library is open from 9 a. m. to 10 p. m. on all week days except holidays throughout the year except during July and August when the hours are 9 a. m. to 6 p. m.

BOOK NOTICES JULY 1-31, 1921

Unless otherwise specified, books in this list have been presented by the publishers. The Society does not assume responsibility for any statements made; these are taken from the preface or the text of the book.

All the books listed may be consulted in the Engineering Societies Library.

THE AIRCRAFT HANDBOOK.

By Fred H. and Henry F. Colvin. Second edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1921. 415 pp., illus., 8 x 5 in., cloth. $4.00.

This work was first published in 1918 under the title, "The Aircraft Mechanics' Handbook," and was intended to meet the wartime need for a book for airplane mechanics. It has now been thoroughly revised and increased in scope to meet the needs occasioned by the development of commercial aviation.

The book is intended to give a good general knowledge of the principles involved in the design of airplanes and their motors without describing details and to show how both planes and motors are assembled, cared for and repaired.

CERAMICS.

By A. Malinovzsky. N. Y., D. Van Nostrand Co., 1921. 274 pp., tables, 7 x 4 in., cloth. $3.00.

The author of this small volume has attempted to write a condensed account of the silicate industries, including methods for silicate analysis and ceramic calculations, which will assist those engaged in the manufacture of clay products to solve the various mathematical problems that arise.

DIE DRAHTSEILBAHNEN.

By P. Stephan. Dritte auflage. Berlin, Julius Springer, 1921. 459 pp., illus., 9 x 6 in., cloth. 150M.

This work is presented as a complete treatise on wire ropeways. The first chapter is devoted to a historical account of their development. This is followed by a description of the various details, such as cables, towers, cars and buckets, landing stations and protective devices. Chapter three gives examples of the use of ropeways for transportation in mountainous lands, for river crossings and as conveyers in various industries, while chapter four presents the various types. Chapter six discusses the economic aspects of the subject and legislation. The closing chapter considers erection and operation.

THE ENGINEERS AND THE PRICE SYSTEM.

By Thorstein Veblen. N. Y., B. W. Huebsch, Inc., 1921. 169 pp., 8 x 5 in., cloth. $1.50.

Contents: On the Nature and Uses of Sabotage.—The Industrial System and the Captains of Industry.—The Captains of Finance and the Engineers.—On the Danger of a Revolutionary Overturn.—On the Circumstances which Make for a Change.—A Memorandum on a Practicable Soviet of Technicians.

This series of papers is reprinted from the "Dial" where they appeared during 1919. They discuss certain difficulties involved in the American industrial situation, and present the author's views concerning the way in which they will be solved.

HANDBOOK OF STANDARD DETAILS FOR ENGINEERS, DRAFTSMEN AND STUDENTS.

By Charles H. Hughes. N. Y. and Lond., D. Appleton and Co., 1921. 312 pp., tables, diagrs., 7 x 5 in., cloth. $6.00.

The book is a compilation, in a volume of convenient size, of drawings, tables and formulas of standard details. Included among these are fastenings of various kinds; shafting, clutches, collars, bearings, gearing and other parts of power transmission; pipes, tubes and fittings; rope and chain fittings; structural and miscellaneous details. Much of the material has been furnished by American machine-tool manufacturers and represents their practise. The work is intended for engineers, draftsmen, etc.

HANDBUCH DER INGENIEURWISSENSCHAFTEN.

Part I, Vol. 5. Tunnelbau, by Karl Brandau, Karl Imhof and Ernst Mackensen. 4th edition. Leipzig, Whilhelm Engelmann, 1921, 712 pp., plates, illus., 10 x 7 in., cloth. 56 M.

Part III, Vol. 6. Der Flussbau, by Franz Kreuter. 5th

edition. Leipzig, Wilhelm Engelmann, 1921. 724 pp., plates, illus., 10 x 7 in., cloth. 154 M.

The "Handbuch des Ingenieurwissenschaften" has long been favorably known as one of the most, if not the most ambitious attempts to publish an encyclopedia of civil engineering. Its thirty-seven volumes cover the field in a way suited for use as a reference book for practising engineers, giving concise accounts of modern theory and practise in their particular fields, accompanied by unusually extensive lists of references to the literature on their subjects.

Of the present volumes, that on Tunneling is a revision and enlargement of the edition issued by Dr. Mackensen in 1901, prepared by Dr. Brandau and Dr. Imhof before Dr. Brandau's death in 1917. A supplement by Dr. E. von Willman fills the gap occasioned by unavoidable delay in publication. The volume discusses tunneling in its applications to mining and railroads, covering design and construction, and illustrating the subject by numerous examples of actual construction.

Dr. Kreuter's treatise on river works covers the subject in a broad manner, including the construction of the various works by which natural water courses are regulated or utilized for transportation, for industrial purposes and in agriculture. Careful attention is given to the results of modern experimental work and the resulting scientific theories.

HANDBUCH DES WASSERBAUES.

By Hubert Engels. Zweite auflage. Leipzig, Wilhelm Engelmann, 1921. 2 vol., diagrs., 11 x 7 in.

The first edition of Engel's "Handbuch des Wasserbaues," published in 1914, was intended to meet the lack of a modern work covering the entire field of hydraulic engineering in a uniform manner that would give the reader a satisfactory account of present developments in the many special subjects which are included in that general term.

The work is divided into ten sections treating of the occurrence and movement of water, hydrology, river works, weirs, dams, and water power plants, protection of land, agricultural hydraulic works, navigation, ship locks, river canalization and ship canals, and harbors. Each of these is an extensive summary of modern theory and practise, accompanied by a list of "sources." The needs of the designer of hydraulic works, rather than those of the builder, have been kept in mind, and such topics as municipal water supplies, water purification and groundwaters have not been included.

The second edition has been revised and enlarged.

DIE HOCHSPANNUNGS-GLEICHSTROMASCHINE.

By A. Bolliger. Berlin, Julius Springer, 1921. 82 pp., diagrs, 10 x 6 in., paper. 18 M.

The development of the direct-current power system, so extensive in the earlier period, but less important since its replacement about 1890 by the alternating-current system, is now, the author believes, entering a new epoch where it will again be the more important, chiefly on account of the electrification of railroads. To use it economically, however, considerably higher working voltages must be attained.

The present monograph is devoted to a new machine for generating high-tension direct currents, which has been developed by the author and tested experimentally. This machine combines certain elements of a machine with mechanical commutation and one with rectifiers of the electrical valve type. The theory of the machine is given in detail, its construction described and the results of tests presented.

DER LICHSTROMBEGRIFF UND SEINE ANWENDUNGEN.

By N. A. Halbertsma. Berlin, M. Krayn, 1921. 62 pp., diagrs., 9 x 6 in., paper. 20 M.

The question discussed in this monograph is the comparative advantages of a system of photometric units based upon luminous intensity, in the customary manner, and one based upon light flux. The author concludes that the latter offers many theoretical and practical advantages, sufficient to justify its adoption.

PRINCIPLES OF RADIO COMMUNICATION.

By J. H. Morecroft, assisted by A. Pinto and W. A. Curry. N. Y., John Wiley & Sons., Inc.; Lond., Chapman & Hall, Ltd., 1921. 935 pp., illus., diagrs., 9 x 6 in., cloth. $7.50.

The opening chapters of this treatise discuss the ordinary laws of continuous and alternating-currents circuits, the transient conditions that continually occur in them and the peculiarities in the behavior of circuits when excited by the very high frequencies of radio work. Succeeding chapters cover each important phase of radio art; spark, telegraphy, vacuum tubes, continuous-wave telegraphy, radio telephony, antenna and radiation, wave meters and amplifiers. A considerable portion of the text is devoted to the theory and behavior of the thermionic three-electrode tube. The final chapter gives a short course of elementary experiments for laboratory use. The book is intended as a text-book for college students especially interested in its subject.

PROCEEDINGS OF THE PHILADELPHIA AND NATIONAL CONFERENCES OF THE CONSTRUCTION INDUSTRIES UNDER THE AUSPICES OF THE INDUSTRIAL RELATIONS COMMITTEE OF THE PHILADELPHIA CHAMBER OF COMMERCE AND THE NATIONAL FEDERATION OF CONSTRUCTION INDUSTRIES. Phila., 1921. 254 pp., 11 x 8 in., paper.

This volume presents the proceedings of the conferences held in February, 1921, by the Industrial Relations Committee of the Philadelphia Chamber of Commerce, and that held in March, 1921, by the National Federation of Construction Industries. At these conferences the construction situation was discussed by experienced men drawn from all the classes interested in construction, and an attempt was made to ascertain the economic and industrial readjustments which must be made before stable conditions can be attained.

THE SCIENTIFIC PAPERS OF BERTRAM HOPKINSON.

Collected and arranged by Sir J. Alfred Ewing and Sir Joseph Larmor. Cambridge, University Press, 1921. 480 pp., port., plates., diagrs., tables, 11 x 7 in., cloth. $20.00 (Gift of the Macmillan Co., N. Y.)

This memorial collection of Professor Hopkinson's writings includes all those that the editors consider of permanent importance, the omissions being either publications of transient interest or others adequately represented by papers included in the collection.

The papers here published may be grouped roughly under a few general heads. Two papers, written in conjunction with Sir R. A. Hadfield, describe researches on the magnetic properties of iron and its alloys. Another group of papers deals with the elastic properties of steel and other metals and with elastic hysteresis. A third group discusses various researches on gas engine phenomena, including heat flow and temperature distribution, and gaseous explosions. The remaining papers deal with the dynamics of explosions from a different point of view.

DIE STEUERUNGEN DER DAMPFMASCHINEN.

By Heinrich Dubbel. Zweite auflage. Berlin, Julius Springer 1921. 384 pp., illus., 9 x 6 in., cloth. 69 M.

This is a treatise on the theory and design of valve and reversing gears for reciprocating steam engines, for the use of designers. The discussion is confined chiefly to the modern forms that have been introduced to meet the demands of high steam pressures and increased speeds, and the competition of steam turbines and gas engines. Matter which is only of historical interest has been omitted, but full attention is given to gearing of the types which have proved best fitted to modern requirements. The discussion of reversing gears includes material on locomotives, rolling-mill and hoisting engines.

TRAITE DE BALISTIQUE EXTERIEURE.

By P. Charbonnier. Tome 1. Paris, Gauthier-Villars et Cie, 1921. 637 pp., diagrs., 10 x 6 in., paper. 75 fr.

This is the first of the six volumes in which it is proposed to publish Charbonnier's treatise on external ballistics to which the Poncelet prize was awarded by the French Institute in 1919. The author has planned, at this favorable time, a complete treatise, embracing everything relating to the science, methodically classified and treated in detail, suited to the needs of students of its theory and of practical artillerymen. His book therefore is a summary of our knowledge at the close of the great war.

The present volume, intended as an introduction to the subject, is divided into two parts. The first is a discussion of the three limiting cases of the ballistics problem, motion in a vacuum and rectilinear motion and vertical motion in a resisting medium. The second considers the general theorems of ballistics, and includes the general properties of atmospheric trajectories and the application of analysis to the ballistics problem.

SECTION AND BRANCH MEETINGS

PAST SECTION MEETINGS

Atlanta.—August 4, 1921, Assembly Hall, Carnegie Library. Election of officers as follows: Chairman, J. E. Mellett; Vice-Chairman, Geo. K. Selden, Jr.; Secretary-Treasurer, H. N. Pye; Executive Committee, Geo. A. Iler and C. E. Emerson. Mr. A. M. Schoen, delegate to the Annual Convention of the Institute at Salt Lake City, made an interesting report. Attendance 17.

Baltimore.—July 28, 1921, Field Day, Walbrook Athletic Club. The Section had as its guests the Baltimore Section of the A. S. M. E. At 7 o'clock a picnic supper was served and following the supper an informal meeting was held. Dr. Whitehead announced the result of the recent election and the new Chairman, Mr. D. Burnett, was installed. Dr. Whitehead gave an interesting report of the impressions which he gained at the recent A. I. E. E. Convention at Salt Lake City. Attendance 40.

Chicago.—June 20, 1921, Western Society of Engineers Rooms. Subject: "The Motion Picture's Secret Part in Winning the War." Speaker: Mr. John F. Strickler, of the Picture Service Bureau. Attendance 225.

Los Angeles.—July 5, 1921. Discussion of Institute Section affairs by past chairmen. President Berresford addressed the meeting and discussed Institute affairs in general. The meeting was preceded by a dinner in honor of President Berresford. Attendance 28.

Panama.—July 31, 1921, Cecelia Theatre. Five reels of motion pictures of the International Western Electric Company, were shown—two reels "Forging the Links of Fellowship," and three reels on modern road construction, maintenance, construction and repairs. Attendance 268.

Philadelphia.—June 17, 1921, Highland Park. Joint Philadelphia Sections of A. I. E. E., A. S. M. E. and I. E. S. In the afternoon a baseball game, tennis and golf were indulged in by teams chosen by the A. I. E. E. and the A. S. M. E.

ADDRESSES WANTED

A list of members whose mail has been returned by the postal authorities, is given below, together with the address as they now appear on the Institute records. Any member knowing the present address of any of these members is requested to communicate with the Secretary at 33 West 39th Street.

1.—R. Coelho, 201 West 95th Street, New York, N. Y.
2.—W. F. Gantvoort, Kedongsarie, 84, Soerabaia, Java, Dutch East Indies.
3.—L. E. Given, 72 West Adams Street, Room 634, Chicago, Illinois.
4.—Conrad Jacobson, Hood River, Oregon.
5.—J. M. Keller, Box 121, Sparrows Point, Md.
6.—Harry P. Meyer, 327 East 61st Street, Los Angeles, Cal.
7.—Basil B. Pilcher, 691 East 230th Street, New York, N. Y.
8.—M. J. Pouillon, 95 Straps Street, Gent, Belgium.
9.—Albert G. Scholer, Dundee Lake, N. J.
10.—Martin Tracy, Tunnel Camp, Brittiania Mines, Howe Sound, B. C., Can.
11.—Frank N. Tucker, 551 East 40th Street, Chicago, Ill.
12.—J. F. Warris, U. S. S., S-3 Union Iron Works, San Francisco, Cal.
13.—Harry Wilson, J. G. White Engg. Corp., Marcus Hook, Pa.

EMPLOYMENT SERVICE BULLETIN

OPPORTUNITIES.—Desirable opportunities for service from responsible sources are announced in this Bulletin, and no charge therefor is made.

MEN AVAILABLE.—Under this heading brief announcements (not more than fifty words) will be published without charge to the members. Announcements will not be repeated except upon request received after a period of three months, during which period names and records will remain in the active files.

NOTE.—Notices for the JOURNAL should be addressed to EMPLOYMENT SERVICE, 33 West 39th Street, New York, N. Y., the employment clearing house of the Societies constituting the Federated American Engineering Societies.

Notices for the JOURNAL are not acknowledged by personal letter, but they will usually appear in the next issue that goes to press.

All replies to either "Opportunities" or "Services Available" should be addressed to the key number indicated in each case and forwarded to EMPLOYMENT SERVICE, as above.

Replies received by the bureau after the position to which they refer has been filled will not be forwarded, and will be held by the bureau for one month only.

Information regarding the notices published is on file in the offices of the member societies of the Federated American Engineering Societies.

MEN AVAILABLE

EXPERIMENTER, age 35; married. Fifteen years practical electrical and mechanical experience. Last ten years experimenting and developing. Have large fund of general electrical and mechanical knowledge. Particularly interested in automatic devices requiring electrical control. Position desired where opportunity for advancement could be expected as ability is proved. E-2915.

ELECTRICAL ENGINEER. Technical graduate; three years teaching experience in large engineering college, and four years experience in test and design departments of electrical manufacturer. Position wanted as assistant professor or instructor of electrical engineering in State University. Can teach either theory or in laboratory. Salary not less than $2500. Age 30. Available on 30 days notice. E-2916.

ELECTRICAL GRADUATE, Assoc. A. I. E. E., competent, trustworthy, age 34, six years hydroelectric operation. Desires position as chief operator in small plant or assistant in large. Employed but must get near high school. Prefer location where small farm may be secured near plant as I want to be permanent. E-2917.

SUPERINTENDENT or general foreman, seven years experience in substation and industrial plant installations and maintenance, technical trained. Assoc. A. I. E. E., age 27; married. Available immediately; location immaterial. Wish connection with a large company offering permanent employment with future opportunity for advancement. Good reference furnished. E-2918.

ELECTRICAL ENGINEER, graduate, age 34; married. Experienced in testing, installation, maintenance and design with a little teaching to pass it on to the other fellow. Would prefer

position as maintenance engineer with high grade industrial establishment that desires to have the electrical department run at the maximum of efficiency. E-2919.

ELECTRICAL ENGINEER, age 25; college graduate, three years experience in calculation of transmission lines layout for power and substations, desires position. Available on short notice. Speaks Spanish; willing to go anywhere. E-2920.

ENGINEER AND EXECUTIVE, thoroughly familiar with all phases of utility work, wishes to get in touch with corporation needing such services. Past experience includes eight years as executive engineer for one of the largest utility corporations during its entire development. Capable of working out consolidations. Understands operating and management problems. E-2921.

ELECTRICIAN, age 24; trade school graduate, with seven years experience in marine and maintenance, construction, shop and storage battery repairs, desires a position with opportunity for advancement. Assoc. A. I. E. E. E-2922.

SUPERINTENDENT or foreman of electrical construction and maintenance. Age 35; married. Ten years experience in factory and mines includes construction operation and maintenance. Three years experience in manufacture and testing of a-c. and d-c. motors and generators. Can handle men. Employed, but desire to change. Eastern States preferred. Assoc. A. I. E. E. E-2923.

ELECTRICAL ENGINEERING GRADUATE; age 32; married, desires position with power company where knowledge of operating characteristics of electrical equipment will be useful. Six years testing for one of the largest manufactures of electrical machinery. Four years inspecting machinery U. S. Navy. Associate A. I. E. E. Certified member A. E. E. E-2924.

ELECTRICAL ENGINEER, technical graduate; age 28. Nineteen months G. E. test. Two years industrial experience which includes installation and maintenance of motor-driven pumps, conveyers and hoists. Power plant and transmission line experience. Expert on electrical theory and calculations. Available immediately. References. E-2925.

ELECTRICAL ENGINEER; age 36. Fifteen years electrical and mechanical shop experience. Eight years in charge; used to modern methods. Good organizer and production getter. Desires position as supervisor of electrical or mechanical department or factory. Safety engineer or employment manager. Located in East; available immediately. Salary according to responsibilites. E-2926.

GRADUATE ENGINEER, E. E. degree; age 29; married; good personality; hard worker executive ability; former 1st. Lieut. Army, construction. One year experience with consulting engineer on hydroelectric construction; two years experience on other construction work; two years teaching experience. Assoc. A. I. E. E. Desires position as teacher or with engineering, manufacturing or light and power company. E-2927.

ELECTRICAL ENGINEER, age 32; married; graduate Virginia Polytechnic Institute, 1914. Assoc. A. I. E. E. Teaching experience in physics and mathematics; two years as officer in the Army; two and a half years sales engineer for Westinghouse E. and M. Co. Desires permanent position with engineering, manufacturing or light and power company, or as instructor in electrical engineering or mathematics. Location immaterial. Available after July 31. E-2928.

ELECTRICAL ENGINEER, available for foreign service. Expert on transformer design with broad experience on related problems of transmission, distribution and system protection. Graduate University of Wisconsin. Westinghouse apprentice. Member A. I. E. E. Age 28; married. Detailed experience furnished confidentially. E-2929.

MECHANICAL & POWER ENGINEER, technical graduate, B. S. and M. E., age 29; single. Seven years experience along broad lines, chemical manufacturing, machine shop, metallurgy, sugar engineering, industrial and power plant practise and operation, design, layout, calculations, steam, water, air, heating and distribution, investigation, etc. Has business and executive ability. Desires responsible position. E-2930.

SMALL MOTOR ENGINEER, technically trained. Six years practical experience on all forms of motor production. Expert on fan-motor and allied single-phase work. Would like position as foreman or assistant in test, assembly or other departments with manufacturing corporation. Assoc. A. I. E. E. Highest references. Age 27; married. E-2931.

ELECTRICAL ENGINEER, 1916 Columbia Univ., with executive ability and five years experience. Desires position as electrical engineer with a hydroelectric company or a firm of consulting engineers. Experience includes G. E. test, investigations and reports on power and transmission problems, use of calculating table for network studies, power rates. Salary $2500 to start. E-2932.

GRADUATE ELECTRICAL MECHANICAL ENGINEER, age 28; married. Four years experience in the design and manufacture of electrical machinery. For the last two years in a responsible position. Would like change where there is chance for advancement. E-2933.

POWER ENGINEER OR MECHANICAL SUPERINTENDENT with twenty years experience covering economical operation and maintenance of steam, electric and refrigeration plants, large buildings, manufacturing, pulp and paper mills. Executive ability. At present chief power engineer in charge of three plants. Available after September 1st. Salary commensurate with position. Location immaterial. E-2934.

ELECTRICAL ENGINEER, technical graduate. Broad practical engineering experience, capable and accustomed to handling engineering problems. Ten years experience in power plants and substation design, construction and operation, and electrical construction work. Desires responsible position with engineering, manufacturing or public utility company. Ohio or vicinity preferred. E-2935.

ELECTRICAL ENGINEER; age 24; single; Assoc. A. I. E. E.; technical graduate Mississippi A & M. One year graduate student course Westinghouse, one and one-half years test floor experience Westinghouse, one year Service engineer, office experience. Preferably central station power work. Location immaterial; available on short notice. E-2936.

ELECTRICAL ENGINEER with organized power plant design and construction corps and sales force wishes to represent manufacturers of electrical power plant equipment and supplies in New York territory with sole agency privileges. Have entree into best architect, engineer and contractor offices and large clientele. E-2937.

ELECTRICAL MECHANICAL ENGINEER technical graduate. One year G. E. test and practical electrician. Six years with power plant consulting engineer design, construction steam power plants, substations, industrial power, distribution, analysis and reports old plants. Capable handling all problems application steam and power in rubber, textile, paper and chemical plant. E-2938.

GRADUATE ELECTRICAL ENGINEER; age 30; married. Five years experience including G. E. test, central station test department instructor in radio division of air service and manager of small hydroelectric company. Desires position with hydroelectric company, central station company or firm of consulting engineers. Available on short notice. E-2939.

SALES ENGINEER, age 30; married; graduate electrical engineer with seven years experience storage batteries and welding, desires permanent connection with future rewarded by ability and effort. Available immediately. E-2940.

ELECTRICAL ENGINEER, 9 years central station experience, desires position as electrical engineer or superintendent; central station company, or industrial concern. University graduate, age 35; married. E-2941.

ELECTRICAL ENGINEER; age 34, married, technical graduate degree M. S., light and power industrial applications, installation, operation and maintenance, location Philadelphia, Pa. Would like interview. E-2942.

RECENT GRADUATE of M. I. T. with S. P. and S. M. in Electrical Engineering desires position with some industrial or firm of engineers. Has had 2 years technical teaching and 2 years industrial experience. At present employed as a junior management engineer. Location Eastern Coast. E-2943.

ELECTRICAL ENGINEER. Age 31. Married B. E. and E. E. degrees. Speaks Spanish. Nine years experience in the layout, ordering materials for, installation and operation, of over 200,000 h. p. in miscellaneous electrical equipment, both large and small. Good parallel mechanical experience. Proved organizing and executive ability. Now holding responsible position, but immediately available at a salary of $3600 a year. E-2944.

ENGINEER. Age 26. Desires position as assistant chief or chief engineer of small electrical plant 2000-5000 h. p. Eight years experience as chief electrician, electrical and steam engineer on power plant and industrial work. Operated turbines, corliss engines, automatically stoked boilers and electrical equipment, etc. Can operate precision machine tools. Fair technical education. Any reasonable salary accepted. E-2945.

ELECTRICAL ENGINEER. Technical education. Recently shift engineer in 90,000-kw. hydroelectric plant. Experienced on a-c. and d-c. installation and operation. Desires similar position. Age 28. Assoc. A. I. E. E. E-2946.

SUPERVISOR of Electrical Instrument Department in large plant desires to make a change. Has years of practical experience to back up first class executive, inventive, and designing ability. 14 years as supervisor of shops doing electrical and navigational instrument work, also fine machine shop practise. Associate A. I. E. E. Salary $3500. Services available at short notice. E-2947.

LOOKING FOR OPPORTUNITY, but would prefer work as assistant to an executive. Technical graduate, with three years practical work in engineering departments of power company and Westinghouse. Foreign field welcomed. E-2948.

TECHNICAL GRADUATE of Electrical Engineering course, '21, age 23, desires a position in electrical engineering work, preferably a consulting engineering concern. Have had 4 years practical experience, at shop work, drafting and testing in the electrical line. Available in about one week. E-2949.

YOUNG MAN evening student at City College New York, desires position with electrical concern. Two years experience with a motor manufacturing concern as laboratory assistant, repair man and tester of both individual parts and finished product. One year experience with company manufacturing electrical indicating instruments. Excellent references. E-2950.

SALES ENGINEER or REPRESENTATIVE for Rhode Island and vicinity, permanently located in Providence; desires connection with firm manufacturing commodity of merit requiring the services of a well trained engineer with good business experience. Would consider establishing agency. Age 34, married. E-2951.

TECHNICAL GRADUATE, age 29, desires connection with industrial engineering or power company. Experience in power plant and substation work, switchboards, wiring diagrams. Also in the manufacture of almost anything in the metal line. Single. Assoc. A. I. E. E. E-2952.

TECHNICAL GRADUATE B. S. 1919. Assoc. A. I. E. E., age 25, desires position as

assistant to electrical engineer in power plant or industrial concern. Eighteen months Westinghouse Test, also some electrical experience chiefly radio gained in the army. Energetic worker with plenty of initiative; good trouble shooter. Best of references; now employed; available upon two weeks notice. E-2953.

ENGINEER with technical education, 12 years experience in designing and manufacturing of starting, lighting and ignition equipment, also induction and fan motor experience. E-2954.

METER SUPERINTENDENT, thirteen years with large eastern utilities, desires to make connections with manufacturer as sales organizer in executive capacity in order to round out his experience, or will undertake to establish or reorganize a meter department or testing bureau for a growing company. E-2955.

GRADUATE ELECTRICAL ENGINEER, M. I. T., 1920, age 23, desires position with power company or assistant to chief engineer of large industrial concern. Experienced in steam and electrical testing as well as knowledge of central and substation equipment. Primarily want permanent position with chance of advancement. Location preferred, eastern states. E-2956.

M. I. T. GRADUATE 1918, electrical engineering desires to enter factory management organization in any capacity, where there exists real opportunity for progressive, technically trained man, who can eventually acquire position of responsibility. Previous experience in this line productive of results. Salary at start of secondary importance. Factory must be in Boston or vicinity. E-2957.

ELECTRICAL ENGINEER, age 21, graduate International Correspondence School, 1920, Assoc. A. I. E. E. Experienced in electrical contracting, factory wiring, motor and generator installation and maintenance. Eighteen months experience as first class electrician on construction and maintenance for oil refinery. Position with chance of advancement desired either on electrical construction, public utilities or with consulting electrical engineer. E-2958.

ELECTRICAL ENGINEER, technical graduate. Age 36. Married. Assoc. A. I. E. E. Four years experience in testing, design and maintenance work. Six years as sales engineer of electrical equipment. Desires position as sales engineer or sales manager. Salary $4200. Available on 30 days notice. E-2959.

ELECTRICAL ENGINEER, Master Mechanic. Technical graduate, age 33, married. Ten years experience construction and operation hydroelectric plants, Mexico, Central America, Colorado; mechanical operation metal mines, crushing, cyanide and oil flotation plants; seeks position with established companies or those contemplating construction. Speaks, reads and writes Spanish. Location no object. E-2960.

ENGINEER of broad teaching and industrial experience desires assistant or associate professorship in electrical engineering. Age 36. Two University degrees. E-2961.

MANAGER OR ASSISTANT. Can you profitably employ the services of a man with several years varied experience in the operation of utility properties? If so, we can correspond with mutual benefit. Technical, 36, married, and best of references. Write me today. E-2962.

YOUNG MAN, age 24, single, desires position with large power company as local operator in town of about 4000, with chance to work up to division managership. Four years experience in this work and now in charge of 11,000-volt station. Can also manage commercial end of business. Will begin on salary of $125.00 per month. Location desired Alabama or Tennessee. E-2963.

ELECTRICAL ENGINEER, age 26, technical education, 7 years experience contracting, testing and construction. Last 3 years with electrical traction company in executive capacity in connection with substation construction. Would prefer entering sales organization of electrical manufacturing concern. E-2964.

ELECTRICAL ENGINEER desires position as superintendent for industrial plant, power, or mining company. Experience covers operation, maintenance, and construction in hydroelectric plants, transmission lines, substations, mill and mine. Sound business training and thorough knowledge of Spanish. Age 28. Married. Available September 15th. E-2965.

ELECTRICAL ENGINEER, B. S. degree; age 21; unmarried; 6 months practical experience; good references. Desires connection leading to future responsibility with a power or manufacturing concern. Middle West location preferred but will go anywhere depending on offer. Initial salary immaterial; available on short notice. E-2966.

ELECTRICAL ENGINEER, University of Illinois graduate, 1912. Central station experience on substation design. Transmission line specifications and rights, and power rates and contracts. Industrial plant experience on power, heat and light installations and superintendence of operation. Desires position of stability and with chances for advancement. E-2967.

POSITIONS OPEN

EASTERN TECHNICAL SCHOOL has opening on its teaching staff for instructor in physics and elementary electricity. Young man, graduate of a four year electrical or mechanical engineering course with some practical or teaching experience preferred. The opportunity for advancement excellent. Reply stating age, education and training, experience and salary desired. Location Boston, Mass. X-604.

EASTERN TECHNICAL SCHOOL has opening for instructor in electrical machinery laboratory. Young men, graduates of a four year electrical or mechanical engineering course with some practical or teaching experience preferred. Opportunity for advancement excellent. Reply stating age, education and training, experience and salary desired. Location Boston, Mass. X-622.

INSTRUCTOR in electrical engineering to handle, principally, laboratory courses. Must have had experience as an assistant, or instructor, in a good laboratory. Additional testing experience with a manufacturing company is desirable. Location Northwest. X-629.

GRADUATE ELECTRICAL OR MECHANICAL ENGINEER, 1919, for sales work with oil company. Sales experience desirable. Location New York City. X-682.

TECHNICAL GRADUATE, preferably under 35 years of age, thoroughly conversant with principles, design and construction of high-tension high-frequency oscillatory apparatus such as condensers, oscillators, transformers, etc., which practically means a man with more or less wireless telegraphy experience. This apparatus is not used in wireless work of any kind, but circuits are more similar to wireless than any other types of circuits. There is an unlimited field for development as the process is so connected with the treatment of oils as to lead almost certainly, with its development, to revolutionary changes in many present refinery practises. Give details of past experience, present connections, age, present and anticipated salaries, etc. Location Missouri. X-710.

INSTRUCTOR for electrical engineering subjects. Good engineering training and experience. Location Kansas. X-715.

GRADUATE ELECTRICAL ENGINEERS, over 30 years of age. Experience in cable manufacture while desirable is not essential. Location N. J. X-741.

INSTRUCTOR, three or four years mathematical training, to teach freshman mathematics, college algebra, trigonometry and analytical geometry. Should have doctor's degree in mathematics from a recognized university. Salary depends upon qualifications and experience of man appointed. Send recent photograph and full statement of courses in mathematics studied and credentials regarding experience in teaching and ability in mathematics. Application by letter. Location Middle West. X-752.

INSTRUCTOR wanted for employes' classes in large electric utility corporation. Knowledge of psychological tests and rating scales desirable. Write fully experience and salary required. Location Ill. X-763.

SALES REPRESENTATIVE for New York and vicinity for boiler tube cleaner. Would be expected to make a stack to stack canvass, also report calls to this office to permit of our cooperating with him by means of follow-up letters. Liberal commission and splendid field for the sale of the tool in New York and vicinity. X-769.

ELECTRICAL ENGINEER with experience in investigation and research work, also construction and erection of radio systems. Application by letter only. Location New York City. X-800.

SALES ENGINEER for concern manufacturing boilers. Inquiries are coming in increasing numbers and these appear to indicate the general feeling amongst steam users that now is the time to prepare their power plants for the business boom that is expected to develop rapidly from now on. Sales engineer engaged through F. A. E. S. has earned more than $5000 a year. Location Pa. X-807.

ENGINEER to teach drawing, mathematics, etc. Prefer young man with machine shop experience. Write giving experience and salary desired. Location New York City. Application by letter. X-808.

UNIVERSITY OF WISCONSIN, Electrical Engineering Department, Madison, will appoint two instructors in electrical engineering. Salary $1500 to $1800 for nine months school year. Men with an unusually thorough grasp of fundamental electrical theory and a year or more experience in the engineering or teaching field are desired. X-779.

CORNELL UNIVERSITY has an opening for an instructor in electrical engineering. Must be a university graduate; one or two years practical experience desirable. Opportunity to pursue graduate work. Write school of Electrical Engineering, Ithaca, N. Y., giving qualifications and references. X-809.

RESEARCH ASSISTANT familiar with theory of transmission lines and a-c. machinery. Must be good in mathematics and a fair mechanical designer. Present appropriation for salary is $130 a month for 10 months. Will be allowed to attend a few classes in Cornell University. X-894.

MANAGER of sawmill property in Mexico, pine timber. Must have similar experience, understand operation by railroad and all phases of the business including sales. Mill of 300 M capacity per day. Must speak Spanish and be man of strong personality. Climatic conditions excellent. Location Mexico. X-823.

LOAD DISPATCHER for a large interurban and power company man having some operating experience preferred. Live wires wanted; excellent opportunity for experience and advancement; salary moderate to start. Application by letter. Give age, experience and education; also salary expected. Recent graduate or those with 2 or 3 years educational training desired. Location Central West. X-826.

ELECTRICAL ENGINEER with 2 to 5 years experience as designer on switchboards, substations and wiring diagramming. No vacancy at present. Send record of experience. Location Pa. X-832.

ELECTRICAL ENGINEER, technical graduate, 8 or 10 years experience on design of large generator units. Man with experience on inspecting generators in electrical plant given preference. Position temporary, 6 to 8 months. Location Pa. X-835.

INSTRUCTOR in sophomore drawing, mathematics (calculus), elementary mechanics (statics and dynamics), and mechanism. Opportunity of promotion both in rank and salary for right man. Courses are on cooperative plan, students working alternate four week periods in the in-

dustries. Work is continuous throughout the year, and the teaching staff is employed on a twleve months basis. Vacation of about one month from the middle of August to the middle of September. Write giving education, experience present salary, salary expected, information regarding your personality, and inexpensive photograph, letters of recommendation, references to whom we may write. Location Middle West. X-837.

SUPERVISING CONSTRUCTION ENGINEERS for installation of electrical equipment in power station. At least 10 years experience necessary. Location New York City. X-838.

Draftsman experienced in hydroelectric designs or in general electric drafting. Application by letter. Location Ala. X-840.

GRADUATE ELECTRICAL ENGINEER, preferably with some telegraph or telephone experience, or not having such experience, should have made an unusually good record in college and since graduation. Man without telephone or telegraph experience should not have graduated from an electrical engineering course more than six years ago. Location New York City. X-855.

INSTRUCTOR to teach Regents subjects. Engineering graduate preferred. Location New York. X-860.

PROFESSOR to take charge of department and teach mathematics and physics. Must have at least masters degree and should be a member of the Baptist church. University runs all year round. X-868.

GRADUATE ENGINEER who will be actual head, or dean, of College of Electrical Engineering. Must have industrial experience and organizing ability. Should have approximately $10,000 which would be invested with us so that he would have a personal interest both in the operation of the business and the profits accruing therefrom. Must be strong organizer and a man with a sympathetic viewpoint toward engineering education and young electrical engineers. Location Middle West. X-876.

INSTRUCTOR or ASSISTANT PROFESSOR. Should be graduate chemist or industrial chemist with 2 or 3 years practical experience in electrochemistry amd metallurgy. Location Pa. X-887.

ENGINEER to look after a steam turbine generator, a boiler plant and the electrical apparatus for a factory. The current 440-volt alternating and the plant is situated at Marquette, Michigan. Will be expected to make minor repairs on the motors and electrical equipment and look after the maintenance of the electrical equipment, turbine, and boiler plant. Location Michigan. X-895.

INSTRUCTOR Electrical Engineering to teach laboratory work. Location Washington (State). X-897.

ENGINEERS to take up sales work. Experience in selling unnecessary. Location New York. X-909.

MEMBERSHIP — Applications, Elections, Transfers, Etc.

ASSOCIATES ELECTED AUGUST 16, 1921

ANDERSON, BURTON E., Load Disptacher's Office, Pacific Gas & Electric Co., Oakland; res., 725 Chanslor Ave., Richmond, Cal.
ANDERSON, IDOF, Chief Electrician, Norton Company, New Bond St., Worcester, Mass.
ANGUS, ROY F., Engineering Dept., American Hard Rubber Co., 11 Mercer St., New York, N. Y.
ARCA, PEDRO P., Engineer, Compania de Electricidad del Rio de La Plata, Ltd., La Plata; res., Parral No. 583, Buenos Aires, Arg. Rep.
ATTWOOD, STEPHEN S., Instructor in Electrical Engineering, University of Michigan; res., 1520 Cambridge Road, Ann Arbor, Mich.
BARRETT, J. NICOLSON, Engineer, Otis Elevator Co., 1373 E. 6th St., Cleveland, Ohio.
BEYERSDORFER, FRED A., Tester, Brooklyn Edison Co., Inc.; res., 1831 Catalpa Ave., Brooklyn, N. Y.
BLANCHARD, HENRY, Chief Electrical & Mechanical Engineer, Maracaibo Electric Lighting Co., Maracaibo, Venezuela, S. A.
BOCKUS, GERALD L., Supt. of Power, City of Sherbrooke, 100 Belvedere St., Sherbrooke, Que.
BUCKLIN, A. H., City Electrician, Municipal Heat, Light & Power Distribution, City Hall, Burley, Idaho.
CAMPANARI, EVANGELISTA, Manager, Nicola Romeo & Co., Via 20 Settembre 33, Milan, Italy.
CARELESS, GEORGE M., Foreman Electro Plater, Electric Storage Battery Co.; res., 4426 N. 15th St., Philadelphia, Pa.
CARLSON, EDWIN L., Engineer, Pacific Tel. & Tel. Co., 507 Sheldon Bldg., San Francisco, Cal.
CHAPLEAU, DEAN D., Student Engineer, Testing Dept., General Electric Co.; res., 849 Union St., Schenectady, N. Y.
CHATLEY, CHARLES C., Asst. Electrical Engineer, B. F. Sturtevant Co., Boston; res., 177 Wachusett St., Forest Hills, Mass.
CHRISTEN, ARTHUR E., Superintendent, United Towns Electric Co., Ltd., Harbor Grace, Newfoundland.
COX, HAROLD J., Southern New England Telephone Co., New Haven; res., 251 Center St., West Haven, Conn.
CURTIS, EDWARD C., Engineer, Kansas Gas & Electric Co., Wichita, Kans.
DALY, CARL F., Chief Repairman, New England Tel. & Tel. Co., Arlington; res., 22 Jackson St., Medford Mass.
DEE, F. KYRL, Electrical Supt., Stock & Dee, 249 W. 14th St.; res., 204 W. 14th St., New York, N. Y.
DEREMER, JAMES S., Pilot Engineer, D. & R. G. R. R.; res., 330 E. 19th St., Denver Colo.
DUSTE, ARTHUR W., Asst. Plant Engineer, Mountain States Tel. & Tel. Co., Denver, Colo.
EARLE, RALPH P., Central High School, Philadelphia; res., Primos, Delaware Co., Pa.
FAHNING, OTTO R., Electrical Designer, Stone & Webster, Inc., Boston Mass.; The American Sugar Refining Co., Consulting Board, 117 Wall St., New York, N. Y.
FOCHT, ALBERT W., Equipment Installer, Western Union Telegraph Co., Chamber of Commerce Building, Denver, Colo.
FULMER, WILLIAM A., Electrical Contractor, 2140 N. 12th St., Philadelphia, Pa.
GASCOIGNE, LOUIS, Supt., Fire Alarm Telegraph, City of Detroit; 647 E. Larned St., Detroit, Mich.
GILLIS, MELVIN D., Foreman, Air Compressor Testing Dept., General Electric Co.; res., 849 Napier Place, Lawrence Park, Erie, Pa.
GLASSE, ALFRED O., Asst. Engineer, with National Electrical & Engineering Corp., Dunedin, New Zealand.
GORDON, BERT E., Power Plant Supt., Utah Power & Light Co., Ogden, Utah
GOULD, HARRY A., Power Plant Engineer; 3999 Greenwood Ave., Oakland, Cal.
GRANER, GEORGE S., Foreman of Electric Construction, Phoenix Utility Co., Hazelton, Pa.
GUPTA, AMULLYA R., Foreman Electrician, Tata Iron & Steel Co. Ltd., P 6 Bungalow, P. O., Jamshedpur (via) Tatanagor, B. N. Ry., India.
HALL, ARTHUR B., Assembler, American Radio & Research Corp.; res., 15 William St., Medford, Mass.
HARMAN, EDWIN N., Automatic Switchman, New York Telephone Co., 121 Castle St.; res., 93 Lyceum St., Geneva, N. Y.
HARRIS, FRANK ST. C., Power Engineer, Clarke Bros. Ltd., Deep Brook, Nova Scotia.
HART, WILLIAM A., Chief Electrician, Phelps Dodge Corp., Stag Canon Branch, Dawson, New Mexico.
HATTINGH, JOHANNES T., Lecturer in Electrical Engineering, Technical College, Durban; res., Elandsfantein, Tarkastad, Union of South Africa.
HEATH, RALPH S., Sales Engineer Agent, General Electric Co., 720 Newhouse Bldg., Salt Lake City Utah.
HEMINGWAY, HARRY A., Cost Estimator & Analyst, General Electric Co., Lynn, Mass.
HENNEFER, ARTHUR McALLISTER, Electrical Contracting, 270 Downington Ave., Salt Lake City, Utah.
HEUSSER, EMIL, General Director, Fabrik Elektrischer Apparate, Sprecher & Schuh, A. G., Arrau, Switzerland.
*INYOUE, NOBORU, Student, Johns Hopkins University, Baltimore, Md.
JENSEN, MARION A., Iowas Service Co., Missouri Valley, Iowa.
JIMBO, SCIKICHI, Engineer of Electro-Technical Laboratory, Dept. of Communication, Tokyo, Japan.
JOHNSON, ARTHUR C. K., Sales Engineer, V. V. Fittings Co., 308 S. Canal St., Chicago, Ill.
JOHNSON, CHESLEY H., Professor in Science Dept., Northeast High School, Philadelphia; res., Summit Ave., Primos, Penn.
JONES, ALBERT F., Office Manager, C. H. Parker & Son Electric Co., 1520 Wazee St.; res., 2547 W. 29th Ave., Denver, Colo.
JONES, FREDERIC P., Electrical Engineer, Anglo-Newfoundland Development Co. Ltd., Grand Falls, N. F.; res., 136 Summer St., Biddeford, Maine.
JONES, SAMUEL W., Division Foreman, Bingham Div., Utah Power & Light Co., Bingham Canyon, Utah.
KAELBER, J. GEORGE, President & General Manager, Interstate Public Service Corp., 1028-1030 Granite Bldg., Rochester, N. Y.
KISSEL, WALTER P., Wire Chief, Mountain States Tel. &. Tel. Co.; res., 419 30th Street, Ogden, Utah.
KNOTT, CHARLES E., Valuation of Electric Power Plants & Substations, Pacific Gas & Electric Co., San Francisco; res., 1813 Bonita St., Berkeley, Cal.
KUHNS, JOHN H., Salesman, Hi-Voltage Equipment Company, 3305 Croton Ave., Cleveland, Ohio.
KULKA, EUGENE R.; res., 163 Lee Ave., Brooklyn, N. Y.
LANGFORD, WILBUR H., Acting Superintendent, Utah Power & Light Co., Preston, Idaho.
LATORRE, ROBERT J., Testing Dept., General Electric Co., 26 Nott Terrace, Schenectady, N. Y.
LINE, RICHARD, Chief Electrical Engineer, Simla Municipality, Simla, Punjab, India.
LIUNGE, PAUL, Engineering Dept., New York Edison Co., 130 E. 15th St., res., 61 Hamilton Place, New York, N. Y.

MACKLER, LOUIS, Asst. Leading Electrical Draftsman, New York Edison Co., 130 E. 15th St., New York, N. Y.
*MARION, FREDERICK R., Long Lines Engg. Dept., American Tel. & Tel. Co., Room 215, 195 Broadway, New York, N. Y.
MARLOWE, THOMAS, Draughtsman, Public Works Dept.; res., 600 Cashel St., Christchurch, N. Z.
MARTI, OTHMAR K., Electrical Tester, Allis-Chalmers Mfg. Co., Milwaukee; res., 512 68th Ave., West Allis, Wis.
MORTON, THOMAS Q., Supt., Power Plant; Assoc. Professor Mechanical Arts, Prairie View State Normal, Prairie View, Texas.
MOSS, ARTHUR E., Electrical Engineer, Kaponga Town Board, Kaponga, N. Z.
MUELLER, EDWIN, Supt., C. J. & F. E. Briner, 1607 Morgan St., St. Louis, Mo.
McCORMICK, ROLLIN D., Engineer, Western Electric Co., Hawthorne; res., 14 N. Ashland Ave., La Grange, Ill.
NORTH, JOHN R., Substation Operator, Southern California Edison Co., 423 S.-M. Blvd. Sawtelle, Cal.
PAGEL, CLARENCE J., Salesman, The Robbins & Myers Co., 408 Marshall Bldg., Cleveland, Ohio.
PELTON, WILLIS H., Dept. of Building & Maintenance, General Electric Co.; res., 1033 Smithson Ave., Lawrence Park, Erie, Pa.
PERRY CHARLES T., Electrical Engineer, City of New York, Dept. of Plants & Structures, St. George, S. I.; res.; 224 Wardwell Ave., Westerleigh, S. I., N. Y.
PRATT, CHESTER C., Supt., Utah Plant Mountain States Tel. & Tel. Co.; res., 933 Lincoln St., Salt Lake City, Utah.
RANDALL, ERNEST G., Electrical Repairman, Shepard Electric Crane & Hoist Co., Montour Falls, N. Y.
RICHARDS, OTHO C., Foreman, Motor Winding Dept., Wagner Electric Mfg. Co.; res., 6325 Spencer Place, St. Louis, Mo.
RIGGS, OLIVER T., Inspector, United Electric Light & Power Co., 514 W. 147th St., New York, N. Y.
ROSE, OTTO K., Instructor, Cass Technical High School, Detroit, Mich.
ROSENBERG, ABRAHAM, Electrical Engineer, The Tarf Co., 11-13 W. 113th St., New York, N. Y.
SCHAMBERGER, SANFORD O., Student Engineer, Testing Dept., General Electric Co.; res., 103 Seward Place, Schenectady, N. Y.
SCHIEMER, EDWARD W., Electrician, McCall Publishing Co., 236 W. 37th St., New York; res., 169 Park Ave., E. Rutherford, N. J.
SCHRYVER, FRANK J., Asst. Wire Chief, Western Union Telegraph Co., Dickinson, N. Dakota.
SCHANK, ROY B., Telegraph Engineer, American Tel. & Tel. Co., 195 Broadway, New York; res., 199 Stryker Ave., Woodside, N. Y.
STECK, M. M., Plant Engineer, Mountain States Tel. & Tel. Co., Salt Lake City, Utah.
STEPHENS, WILLIAM T., Engineer's Assistant, Operating Research Bureau, The Milwaukee Electric Railway & Light Co., Milwaukee; res., 226 Greenfield Ave., Wauwatosa, Wis.
TAGGART, WILLARD T., Electrical Inspector, Western Electric Co., 598 Finance Bldg., Philadelphia; res., Marietta, Pa.
TAYLOR, CLARENCE M., Asst. Supt., The Lincoln Electric Co., Cleveland; res., 1852 Charles Road, E. Cleveland, Ohio.
THOMPSON, EARL L., Chief Operator, The Depew & Lancaster Light Power & Conduit Co.; res., 45 School St., Lancaster, N. Y.
TOMLINSON, CARROLL M., Engineering Asst., Plant Dept., The Bell Telephone Co. of Pa., Pittsburgh; res., 909 James St., Wilkinsburg, Pa.
TUSH, JAMES W., Superintendent, Municipal Electric Light & Power; res., 125 N. 8th St., Martins Ferry, Ohio.
TWYMAN, NEAL, Electrician, Colorado United Mines Co., Wall Street, Colo.
VAN NORMAN, JAMES W., Asst. Work's Engineer, Canadian Explosives Ltd., James Island, B. C.
VEATCH, JAMES S., District Sales Manager, The Ohio Brass Co.; res., 536 Downing St., Denver, Colo.
VENKATARAM, V., Asst. Electrical Engineer, Walker, Sons & Co., Ltd.; c/o Postmaster, Nungavarm Post, via Trichinopoly, S. India.
WAGNER, GEORGE, Junior Electrical Engineer, Public Service Commission, 45 Lafayette St., New York; res., 34 Edson St., Corona, L. I., N. Y.
WHITALL, CHARLES W., White Oak Farm, Pawling, N. Y.
WICHMAN, RALPH D., 3155 Clay St., San Francisco, Cal.
WILCH, NOLE H., Repeater Attendant, American Tel. & Tel. Co.; Beaver Dam, Ohio.
WILLIAMS, JEROME H., Asst. Engineer, Interborough Rapid Transit Co., 600 W. 59th St.; res., 189 Claremont Ave., New York, N. Y.
YARLETT, WILBUR R., Instructor, Carnegie Institute of Technology, Pittsburgh; res., 435 Ella St., Wilkinsburg, Pa.
YATES, RAYMOND F., Associate Editor, Popular Science Monthly, 225 W. 39th St.; res., 81 Northern Ave., New York, N. Y.

*Former Enrolled students.

ASSOCIATES REELECTED AUGUST 16, 1921

HICKS, GEORGE E., Superintendent, The Syndicate Mining & Milling Co., Rico, Colo.
HIGSON, CHARLES R., Asst. to General Supt., Utah Power & Light Co.; res., 1224 E. 3rd South, Salt Lake City, Utah.
HOPKINS, ALFRED H., Chief Electrician, Consolidated Mining & Smelting Co., Trail, B. C.
JOHNSTONE, DOUGLAS M., Chief Operating Engineer, British Columbia Electric Railway Co., Ltd., Vancouver, B. C.
LANCASTER, JOHN G., Chief Electrical Engineer, Hay & Vickerman, Wellington, N. Z.
NIETHAMMER, FRIEDRICH, Professor of Electrical Engineering, German Technical University, Prag 1, Bohemia.
SHAVER, GEORGE W., Electrical Engineer, Utah-Idaho Central Railway; res., 638 23rd St., Ogden, Utah.

MEMBERS ELECTED AUGUST 16, 1921

AINSWORTH, CHESTER D., Chief Design Engineer, Condit Electrical Mfg. Co., S. Boston; res., 57 Phillips St., Wollaston, 70, Mass.
ALEXANDER, JAMES P., Sales Engineer Westinghouse Electric & Mfg. Co., New Haven, Conn.
BINDSHEDLER, THEODORE S., Electrical Engineer, Burroughs Adding Machine Co.; res., 1455 W. Philadelphia Ave., Detroit, Mich.
BREDBERG, STEN, Switchboard Engineer, General Electric Co.; res., 521 Lenox Road, Schenectady, N. Y.
CECCARINI, OLINDO O., Radio Designing Section, Western Electric Co., 463 West St.; res., 271 W. 12th St., New York, N. Y.
CHANG, TING CHIN, Professor of Electrical Engineering, Government Institute of Technology, 862 Siccawei Road, Shanghai, China.
DALZELL, HAROLD E., Chief Mechanical & Electrical Engineer, Southern Railways of Peru & Dependencies, Arequipa, Peru.
DYER, JOHN B., Electrical Engineer, Automotive Dept., Wagner Electric Mfg. Co., St. Louis; res., 135 Wesley Ave., Ferguson, Mo.
GUTHERZ, MARSHALL F., Manager, Electrical Dept., William H. Taylor & Co., 250-256 Hamilton St., Allentown, Pa.
JACKSON, EARLE D., Consulting Enginee 403 Endicott Bldg., St. Paul, Minn.
JOURDAIN, JAQUES, Director General, Campagnie Lorraine, d'Electricite, 64, Rue du Faubourg Stanislas, Nancy, France.
KORTHEUER, H. FRANCIS, Division Head, Engineering Dept., Western Electric Co., 463 West St., New York, N. Y.
LAUNDER, JOHN E., President, Independent Electric Machinery Co., N. E. Cor. 20th & Central Sts., Kansas City, Mo.
MARTINDALE, ROY, Asst. Operating Engineer, Bureau of Power & Light; res., 1026½ N. Alvarado St., Los Angeles, Cal.
REYNOLDS, LEWIS C., Electrical Engineer, Empire Gas & Electric Co., Geneva; res., 12 Tuxill Square, Auburn, N. Y.
STANSELL, GEORGE H., Electrical Engineer, Fisher-Body Ohio Co.; res., 13816 Coit Road, Cleveland, Ohio.
WALSH, N. STEVEN, Electrical Engineer, A. A. Giddings & Co., Ltd., 660 Dorchester St. West, Montreal, Que.
WALTER, ROSCOE G., Asst. General Superintendent, Wisconsin Power, Light & Heat Co.; res., 424 W. Wilson St., Madison, Wis.
WATERMAN, JOHN H., Mechanical & Electrical Engineer, Charles T. Main, 201 Devonshire St., Boston, Mass.
WEST, JAMES O., Electrical Engineer, The Willys Morrow Mfg. Co., Elmira; res., Wellsburg, N. Y.

TRANSFERRED TO GRADE OF FELLOW, AUGUST 16, 1921

BAILEY, BENJAMIN F., Professor of Electrical Engineering, University of Michigan, Ann Arbor, Mich.
FORTESCUE, CHARLES L., Electrical Engineer, Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.
HERZ, ALFRED, Engineer of Electrical Tests, Public Service Co. of Northern Illinois, Chicago, Ill.
LAWSON, CHARLES S., Section Engineer, Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.
WYMAN, FRANK T., President, Packard Electric Co., Ltd., St. Catharines, Ont.

TRANSFERRED TO GRADE OF MEMBER, AUGUST 16, 1921

BAER, FREDERICK L., Contract Sales Engineer, Automatic Electric Co., Chicago, Ill.
BEATTYS, WILLIAM H., Jr., Representative, Westinghouse Traction Brake Co., Chicago, Ill.
COLE, JAMES L., Asst. Superintendent, Westinghouse Elec. & Mfg. Co., Newark, N. J.
CROFT, TERRELL, Directing Engineer, Terrell Croft Engineering Co., St. Louis, Mo.
GUILDFORD, CHARLES T., General Engineer, Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.
LAWSON, JOEL S., Sales Engineer, R. Thomas & Sons Co., New York, N. Y.
LEWIS, DONALD M., Secretary & Treasurer, General Manager & Chief Engineer, Livingston-Niagara Power Co., Avon, N. Y.
MARTIN, WILLIAM H., Dept. of Development and Research, American Telephone & Telegraph Co., New York, N. Y.
OSBORNE, CHARLES P., Supt. of Light & Power, Portland Railway, Light & Power Co., Portland, Ore.
ROBBINS, ARTHUR H., Supt. of Distribution, Electric Light & Power Co. of Abingdon & Rockland, North Abingdon, Mass.
RUSSELL, HERBERT A., Designing Engineer, Toronto Hydro-Electric System, Toronto, Ont.
TERVEN, LEWIS A., Electrical Engineer, Switchboard Dept., Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.
THAU, WALTER E., Engineer, Marine Section, Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

WAGNER, EFFINGHAM B., Electrical Engineer, Lehigh Valley Coal Co., Wilkes-Barre, Pa.
WELLS, JAMES H., Chief Electrical Draftsman, Brooklyn Edison Co., Brooklyn, N. Y.

RECOMMENDED FOR TRANSFER

The Board of Examiners, at its meetings held June 10 and August 8, 1921, recommended the following members of the Institute for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the Secretary.

To Grade of Member

BRUEGGEMAN, FRANK, Asst. Mechanical & Electrical Engineer, South Park Commissioners, Chicago, Ill.
CHRISTIANSEN, KAY C., Electrical Engineer & Supt. of Elec. Construction, Phoenix Utility Co., Hazleton, Pa.
COLVIN, C. W., Asst. Appraiser & Chief Engineer, Appraisal Dept., British Columbia Electric Ry. Co., Ltd., Vancouver, B. C.
CONDON, EDWARD J., President, Condon Engineering Co., Chicago, Ill.
CURTIS, ALFRED S., Telephone Engineer, Western Electric Co., New York, N. Y.
DAVIDSON, JOHN, Jr., Telephone Engineer, American Telephone & Telegraph Co., New York, N. Y.
DEMAREST, CHARLES S., Electrical Engineer, American Telephone & Telegraph Co., New York, N. Y.
FAIRLEY, G. E. A., Engineer, Buildings and Grounds, Carnegie Institute of Technology, Pittsburgh, Pa.
FIELD, CROSBY, Engineering Manager, National Aniline & Chemical Co., Inc., New York, N. Y.
HALL, GERALD R., Engineer, Apparatus Sales Dept., Canadian General Electric Co., Toronto, Ont.
HAMDI, ABDULLAH F., General Foreman, Test Dept., New York Edison Co., New York, N. Y.
KITTREDGE, CARLYLE, Chief Engineer, Michigan State Telephone Co., Detroit, Mich.
LANCASTER, JOHN G., Chief Electrical Engineer, Hay & Vickerman, Wellington, New Zealand.
MANVEL, FREDERIC I., Installation Engineer, General Electric Co., Pittsfield, Mass.
MORGAN, FRED, Electrical Engineer, Sessions Engineering Co., Chicago, Ill.
NEWLIN, EARL M., Engineer, Superpower Survey, U. S. Geological Survey, New York, N. Y.
PAGE, ROY, General Superintendent, Nebraska Power Co., Omaha, Neb.
PARSONS, OLIN D., Telephone Engineer, Western Electric Co., New York, N. Y.
PLUMB, HYLON T., Local Engineer, General Electric Co., Salt Lake City, Utah.
PROEBSTEL, D. W., Asst. Engineer, Portland Railway Light & Power Co., Portland, Ore.
RAKESTRAW, CLAUDE N., Supt. of Lines, Cleveland Electric Illuminating Co., Cleveland, O.
SUTHERLAND, WILLIAM F., Designing Engineer, Toronto Hydroelectric System, Toronto, Ont.
WARWICK, JOHN F., Engineer, Georgia Railway & Power Co., Atlanta, Ga.
WELLER, CLIFFORD T., Engineer, General Engineering Laboratory, General Electric Co., Schenectady, N. Y.
WORK, WILLIAM R., Prof. of Elec. Engineering, Carnegie Institute of Technology, Pittsburgh, Pa.

APPLICATIONS FOR ELECTION

Applications have been received by the Secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a higher grade than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the Secretary before August 31, 1921.

Aubert, Francis, Mexico City, Mexico.
Bell, Trice M., Schenectady, N. Y.
Bond, T. Kirk, Tooele City, Utah.
Bush, Clarence R., Peoria, Ill.
Butler, V. Dell, Bull Run, Ore.
Castro, Jorge E., Mexico City, Mexico.
Cox, A. Walter, Youngstown, Ohio
Cunningham, John T., Brooklyn, N. Y.
Friend, Henry M., Brooklyn, N. Y.
Fukami, Gen-ichiro, New York, N. Y.
Gardner, Murray F., Lansing, Mich.
Gill, Clarence R., Chicago, Ill.
Gruner, Raymond W., Milwaukee, Wis.

STUDENTS ENROLLED AUGUST 16, 1921

13515 Ellis, Fred D., University of Michigan
13516 Chute, George M., Jr., University of Michigan
13517 Kaphan, Harold H., New York Electrical School
13518 Nordling, William G., Hew York Electrical School
13519 Vogt, Harry E., Mechanics Institute
13520 Hapgood, Kenneth E., Worcester Polytechnic Institute
13521 Thompson, Allan K., University of Southern California
13522 Pape, Erie, Pratt Institute
13523 Ryan, Ambrose A., Montana State College
13524 Michel, Charles J., Pratt Institute
13525 Bulkley, Olcott R., California Institute of Technology
13526 Snow, John G., Worcester Polytechnic Institute
13527 Finkle, George H., University of Wisconsin
13528 Hammatt, Edward R., New York Electrical School
13529 Rogers, Frank M., New York Electrical School
13530 Cody, Martin F., Jr., Cooper Union Night School
13531 Hill, Warren R., Worcester Polytechnic Institute
13532 Stonestreet, Nicholas V., University of Maryland
13533 Brown, Leland H., Stanford University
13534 Mendonca, Marcello P., Stanford Univ.
13535 Miller, Charles E., Stanford University
13536 West, William V., Stanford University
13537 Pearlmutter, Harry J., Tufts College
13538 Cline, Leon H., Clarkson College
13539 Koontz, Rufus G., University of North Carolina
13540 Culin, Harold G., Carnegie Institute of Technology
13541 Collier, Wilbur H., Johns Hopkins Univ.
13542 Lazarus, Louis, Brooklyn Polytechnic Inst.
13543 Lawrence, William D., Newark Technical School
13544 Hadlock, Perry F., Clarkson College of Technology
13545 Petty, Louis, New York Electrical School
13546 Harper, Alfred C., New York Eleotrical School
13547 Sidwell, Richard E., Drexel Institute
13548 Miller, Clifford K., Drexel Institute
Total 34

OFFICERS OF A. I. E. E. 1921-1922

PRESIDENT.
(Term Expires July 31, 1922)
WILLIAM McCLELLAN

JUNIOR PAST-PRESIDENTS

(Term expires July 31, 1922)	(Term expires July 31, 1923)
CALVERT TOWNLEY	A. W. BERRESFORD

VICE-PRESIDENTS

(Terms expire July 31, 1922)	(Terms expire July 31, 1923)
W. A. HALL	N. W. STORER
W. A. DEL MAR	C. G. ADSIT
J. C. PARKER	F. W. SPRINGER
H. W. EALES	ROBERT SIBLEY
O. B. COLDWELL	F. R. EWART

MANAGERS.

(Terms expire July 31, 1922)	(Terms expire July 31, 1923)
WALTER I. SLICHTER	L. E. IMLAY
G. FACCIOLI	F. F. FOWLE
FRANK D. NEWBURY	L. F. MOREHOUSE
(Terms expire July 31, 1924)	(Terms expire July 31, 1925)
HAROLD B. SMITH	R. B. WILLIAMSON
JAMES F. LINCOLN	A. G. PIERCE
E. B. CRAFT	HARLAN A. PRATT

TREASURER	SECRETARY
(Terms expire July 31, 1922)	
GEORGE A. HAMILTON	F. L. HUTCHINSON

HONORARY SECRETARY	GENERAL COUNSEL
RALPH W. POPE	PARKER & AARON, 66 Broad Street, New York.

PAST-PRESIDENTS—1884-1921

*Norvin Green, 1884-5-6.
*Franklin L. Pope, 1886-7.
T. Commerford Martin, 1887-8.
*Edward Weston, 1888-9.
Elihu Thomson, 1889-90.
*William A. Anthony, 1890-91.
Alexander Graham Bell, 1891-2.
Frank Julian Sprague, 1892-3.
*Edwin J. Houston, 1893-4-5.
*Louis Duncan, 1895-6-7.
*Francis Bacon Crocker, 1897-8.
A. E. Kennelly, 1898-1900.
Carl Hering, 1900-1.
Charles P. Steinmetz, 1901-2.
Charles F. Scott, 1902-3.
Bion J. Arnold, 1903-4.
John W. Lieb, 1904-5.
Schuyler Skaats Wheeler, 1905-6.
*Samuel Sheldon, 1906-7.
*Henry G. Stott, 1907-8.
Louis A. Ferguson, 1908-9.
Lewis B. Stillwell, 1909-10.
Dugald C. Jackson, 1910-11.
Gano Dunn, 1911-12.
Ralph D. Mershon, 1912-13.
C. O. Mailloux, 1913-14.
Paul M. Lincoln, 1914-15.
John J. Carty, 1915-16.
H. W. Buck, 1916-17.
E. W. Rice, Jr., 1917-18.
Comfort A. Adams, 1918-19.
Calvert Townley, 1919-20.
A. W. Berresford, 1920-21.

*Deceased

LOCAL HONORARY SECRETARIES

Charles le Maistre, 28 Victoria St., London, S. W., England.
Guido Semenza, N. 10 Via S. Radegonda, Milan, Italy.
Robert Julian Scott, Christchurch, New Zealand.
T. P. Strickland, 61 Hunter St., Sydney, N. S. W.
W. G. T. Goodman, Adelaide, South Australia.
L. A. Herdt, McGill Univ., Montreal, Que.
A. S. Garfield, 10 Rue de Londres, Paris, France.
Harry Parker Gibbs, Tata Hydroelectric Power Supply Co., Ltd., Bombay, India.
John W. Kirkland, Johannesburg, South Africa.

A. I. E. E. COMMITTEES

GENERAL STANDING COMMITTEES

EXECUTIVE COMMITTEE
William McClellan, Chairman, 1628 Real Estate Trust Bldg., Philadelphia, Pa.
W. A. Del Mar, George A. Hamilton, W. I. Slichter,
Walter A. Hall, L. F. Morehouse, Calvert Townley.

FINANCE COMMITTEE
L. F. Morehouse, Chairman, 195 Broadway, New York.
H. W. Eales, Harlan A. Pratt.

MEETINGS AND PAPERS COMMITTEE
E. E. F. Creighton, Chairman, General Electric Co., Schenectady, N. Y.
J. C. Clark, S. P. Grace, F. D. Newbury.
L. W. W. Morrow,
Chairman of Committee on Coordination of Institute Activities.
Chairmen of Technical Committees.
Chairmen of Sections.

PUBLICATION COMMITTEE
A. S. McAllister, Chairman, 248 W. 76th St., New York.
E. E. F. Creighton, F. L. Hutchinson, L. F. Morehouse.
Donald McNicol,

COMMITTEE ON COORDINATION OF INSTITUTE ACTIVITIES
W. I. Slichter, Chairman, Columbia University, New York.
E. E. F. Creighton, F. L. Hutchinson, L. F. Morehouse.
A. S. McAllister,

BOARD OF EXAMINERS
H. H. Norris, Chairman, 217 Inwood Ave., Upper Montclair, N. J.
Philander Betts, Donald McNicol, N. L. Pollard,
Wm. A. Del Mar, J. H. Morecroft, E. M. Sawtelle,
Erich Hausmann, H. S. Wynkoop.

SECTIONS COMMITTEE
John B. Fisken, Chairman, Box 2158, Spokane, Wash.
C. Francis Harding, Vice-Chairman
A. W. Berresford, J. C. Parker. J. Lloyd Wayne.
Chairmen of all Sections.

COMMITTEE ON STUDENT BRANCHES
C. Francis Harding, Chairman, Purdue University, Lafayette, Ind.
A. C. Lanier, C. E. Magnusson, Harold B. Smith.
Charles F. Scott,

MEMBERSHIP COMMITTEE
E. H. Martindale, Chairman, Martindale Electric Co., Station G., Cleveland, O.
Vice-Chairmen:
R. L. Dodd, F. L. Kemp, John Salberg,
D. B. Fleming, J. E. Macdonald, M. E. Skinner,
R. B. Howland, George H. Middlemiss, J. L. Woodress,
W. N. Ryerson,
Chairmen of local Section membership committees.

HEADQUARTERS COMMITTEE
W. A. Del Mar, Chairman, Habirshaw Elec. Cable Co., Yonkers, N. Y.
F. L. Hutchinson, L. F. Morehouse.

LAW COMMITTEE
H. H. Barnes, Jr., Chairman, 120 Broadway, New York.
Frank R. Ewart, P. Junkersfeld, Charles A. Terry.
L. F. Morehouse,

PUBLIC POLICY COMMITTEE
H. W. Buck, Chairman, 49 Wall St., New York.
Gano Dunn, John W. Lieb, Calvert Townley.
C. E. Skinner,

COMMITTEE ON CODE OF PRINCIPLES OF PROFESSIONAL CONDUCT
C. A. Adams, Chairman, Harvard University, Cambridge, Mass.
A. H. Babcock, George F. Sever, Schuyler Skaats Wheeler.
L. B. Stillwell,

COMMITTEE ON SAFETY CODES
H. B. Gear, Chairman, 72 W. Adams St., Chicago, Ill.
H. C. Cushing, M. G. Lloyd, Farley Osgood,
J. C. Forsyth, Wills Maclachlan, H. R. Sargent,
H. O. Lacount, R. W. E. Moore, A. M. Schoen,
Johnston Livingston, H. N. Muller, H. S. Warren.

STANDARDS COMMITTEE
Harold Pender, Chairman, University of Pennsylvania, Philadelphia, Pa.
G. A. Anderegg, Percy E. Hart, F. D. Newbury,
Frederick Bedell, H. M. Hobart, H. S. Osborne,
B. A. Behrend, Dugald C. Jackson, S. G. Rhodes,
L. F. Blume, P. Junkersfeld, Charles Robbins,
G. A. Burnham, G. L. Knight, L. T. Robinson,
E. J. Cheney, F. A. Laws, R. F. Schuchardt,
L. W. Chubb, C. O. Mailloux, C. E. Skinner,
F. P. Cox, C. S. McDowell, Arthur B. Smith,
E. B. Craft, W. L. Merrill, N. W. Storer,
W. A. Del Mar, J. F. Meyer, John B. Taylor,
F. M. Farmer, Taliaferro Milton, A. H. Timmerman,
H. W. Fisher, R. W. E. Moore, Philip Torchio
F. C. Hanker, L. F. Morehouse, W. K. Vanderpoel,
R. B. Williamson.

EDISON MEDAL COMMITTEE
Appointed by the President for term of five years.
(Term expires July 31, 1922)
Comfort A. Adams, Chairman,
L. A. Ferguson, S. W. Stratton.
(Term expires July 31, 1923.)
Frederick Bedell, L. T. Robinson, Calvert Townley,
(Term expires July 31, 1924.)
E. D. Adams, H. H. Barnes, Jr. B. G. Lamme.
(Term expires July 31, 1925.)
H. M. Byllesby, D. E. Drake, W. L. R. Emmet.
(Term expires July 31, 1926.)
B. A. Behrend, John H. Finney, C. S. Ruffner.
Elected by the Board of Directors from its own membership for term of two years
(Term expires July 31, 1922.)
L. E. Imlay, F. D. Newbury, W. I. Slichter.
(Term expires July 31, 1923.)
A. W. Berresford, L. F. Morehouse, R. B. Williamson.
Ex-Officio
Wm. McClellan, President. George A. Hamilton, Treasurer,
F. L. Hutchinson, Secretary.

RESEARCH COMMITTEE
F. B. Jewett, Chairman, 463 West St., New York, N. Y.
B. A. Behrend, Bancroft Gherardi, E. W. Rice, Jr.
Frederick Bedell, D. C. Jackson, Clayton H. Sharp,
F. S. Clark, P. Junkersfeld, C. E. Skinner,
E. B. Craft, A. E. Kennelly, Elmer A. Sperry,
E. E. F. Creighton, John B. Klumpp, Schuyler Skaats Wheeler,
H. P. Davis, M. G. Lloyd, John B. Whitehead,
W. A. Del Mar, L. F. Morehouse, W. R. Whitney.

TECHNICAL COMMITTEES

EDUCATIONAL
C. E. Magnusson, Chairman, University of Washington, Seattle, Wash.
W. C. Bauer, Charles S. Howe, R. F. Schuchardt,
Edward Bennett, John C. Parker, W. L. Upson,
C. R. Dooley, G. H. Pfeif, Wm. R. Work.
H. W. Price,

ELECTRICAL MACHINERY
B. A. Behrend, Chairman, 85 Devonshire St., Boston, Mass.
B. L. Barns, V. A. Fynn, A. S. McAllister
R. E. Brown, David Hall, F. D. Newbury,
James Burke, H. U. Hart, Philip Torchio,
G. Faccioli, V. Karapetoff, Herman L. Wallau,
W. J. Foster, Paul Lincoln, R. B. Williamson.

ELECTROCHEMISTRY AND ELECTROMETALLURGY
Lawrence Addicks, James J. Farley, W. H. Powell,
F. G. Clark, Carl Hering, J. A. Seede,
I. R. Edmands, L. E. Imlay, J. L. Yardley.
F. A. Lidbury,

ELECTROPHYSICS
F. W. Peek, Jr., Chairman, General Electric Co., Pittsfield, Mass.
H. D. Arnold, J. C. Clark, E. P. Hyde,
E. F. Burton, C. P. Eldred, Chester W. Rice,
L. W. Chubb, Charles Fortescue, H. B. Smith.
Roy S. Glasgow,

INDUSTRIAL AND DOMESTIC POWER
W. C. Yates, Chairman, General Electric Co., Schenectady, N. Y.
P. H. Adams, Charles D. Fawcett, A. C. Lanier,
H. W. Cope, C. T. Guildford, M. J. McHenry,
W. E. Date, Henry D. James, A. G. Pierce,
E. D. Doyle, Fraser Jeffrey, H. P. Reed,
C. W. Drake, W. C. Kalb, Leo Schirtzinger,
H. W. Eastwood, C. W. Kincaid Carl F. Scott.

INSTRUMENTS AND MEASUREMENTS
F. V. Magalhaes, Chairman, 55 Duane St., New York, N. Y.
C. W. Baker, F. P. Cox, E. F. Northrup,
P. A. Borden, E. D. Doyle G. A. Sawin,
Wm. M. Bradshaw, A. L. Ellis, H. B. Smith,
H. B. Brooks, H. S. Vassar

IRON AND STEEL INDUSTRY

E. S. Jefferies, Chairman, The Steel Co. of Canada Ltd., Hamilton, Ont.
F. B. Crosby, R. B. Gerhardt, G. E. Stoltz,
Gordon Fox, K. A. Pauly, Wilfred Skyes,
Eugene Friedlaender, D. M. Petty, F. H. Woodhull.
Wm. T. Snyder,

LIGHTING AND ILLUMINATION

C. E. Clewell, Chairman, University of Pennsylvania, Philadelphia, Pa.
G. N. Chamberlin, W. T. Dempsey, B. E. Shackelford,
A. B. Cooper, R. C. Powell, W. M. Skiff,
J. R. Cravath, W. D'A. Ryan. C. H. Stickney.
Charles F. Scott,

MARINE

Arthur Parker, Chairman, N. Y. Shipbuilding Co., Camden, N. J.
J. B. Bassett, H. Franklin Harvey, Jr. I. H. Osborne,
R. A. Beekman, Wm. Hetherington, Jr. G. A. Pierce, Jr.,
Eskil Berg, H. L. Hibbard, H. M. Southgate,
L. C. Brooks, William F. James, W. E. Thau,
Maxwell W. Day, C. A. Jones, E. P. Townsend,
David D. Faris, C. S. McDowell A. E. Waller,
E. G. Gallagher, W. F. Meschenmoser, F. W. Wood.

MINES

Graham Bright, Chairman, W. E. & M. Co., East Pittsburgh, Pa.
Willard C. Adams, L. C. Ilsley, W. F. Schwedes,
R. T. Andrae, G. M. Kennedy, F. L. Stone,
M. C. Benedict, R. L. Kingsland, W. A. Thomas,
H. W. Eales, A. B. Kiser, C. D. Woodward.

POWER STATIONS

H. P. Liversidge, Chairman, Philadelphia Electric Co., 10th & Chestnut Sts., Philadelphia, Pa.
H. A. Barre, H. W. Eales, F. D. Newbury,
J. T. Barron, F. C. Hanker, R. F. Schuchardt,
A. E. Bauhan, P. Junkersfeld, A. B. Stitzer,
E. T. Brandon, W. H. Lawrence, H. R. Summerhayes,
D. H. Braymer, I. E. Moultrop, R. B. Williamson.

PROTECTIVE DEVICES

H. R. Woodrow, Chairman, Stone & Webster Corp., 147 Milk St., Boston, Mass.
G. H. Bragg, E. M. Hewlett, A. G. Pierce,
P. H. Chase, F. L. Hunt, N. L. Pollard,
W. H. Cole, J. B. MacNeill, F. E. Ricketts,
L. N. Crichton, John C. Martin, D. W. Roper,
F. C. Hanker, A. A. Meyer, E. R. Stauffacher,
S. E. M. Henderson, W. H. Millan, E. C. Stone,
E. A. Hester, John B. Taylor.

TELEGRAPHY AND TELEPHONY

Donald McNicol, Chairman, 132 Union Rd., Roselle Park, N. J.
O. B. Blackwell, C. E. Davies, W. O. Pennell,
C. W. Burkett, F. E. d'Humy, Stanley Rhoads,
G. A. Cellar, D. H. Gage, Edgar Russell,
R. E. Chetwood, H. Hulatt, A. E. Silver,
L. W. Chubb, F. H. Kroger, A. B. Smith,
E. H. Colpitts, L. F. Morehouse, F. A. Wolff.

TRACTION AND TRANSPORTATION

A. H. Babcock, E. B. Katte, N. W. Storer,
Reinier Beeuwkes, John Murphy, R. W. Stovel,
R. H. Dalgleish, Hugh Pattison, H. M. Warren,
W. G. Gordon, W. B. Potter, F. E. Wynne,
Selby Haar, Ralph H. Rice, C. W. Young,
Guy A. Richardson.

TRANSMISSION AND DISTRIBUTION

Edward B. Meyer, Chairman, Public Service Electric Co., Newark, N. J.
R. W. Atkinson, John H. Finney, C. N. Rakestraw,
Wallace S. Clark, L. M. Klauber, C. C. Robinson,
W. H. Cole, J. A. Koontz, Jr., D. W. Roper,
W. A. Del Mar, W. S. Lee, A. E. Silver,
H. C. Don Carlos, G. J. Newton, W. K. Vanderpoel,
F. M. Farmer, A. M. Perry, C. T. Wilkinson.

A. I. E. E. REPRESENTATIVES

ON AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE, COUNCIL

H. H. Humphrey, John B. Taylor.

ON AMERICAN BUREAU OF WELDING

W. L. Merrill.

ON AMERICAN COMMITTEE ON ELECTROLYSIS

Bion J. Arnold, N. A. Carle, F. N. Waterman.

ON AMERICAN ENGINEERING COUNCIL OF THE FEDERATED AMERICAN ENGINEERING SOCIETIES

Comfort A. Adams, W. A. Layman, Charles S. Ruffner,
A. W. Berresford, *William McClellan, *Charles F. Scott,
*H. W. Buck, L. F. Morehouse, *L. B. Stillwell,
F. L. Hutchinson, L. T. Robinson, *Calvert Townley.
*Members of Executive Board.

ON AMERICAN ENGINEERING STANDARDS COMMITTEE

Comfort A. Adams, H. M. Hobart, C. E. Skinner,
L. T. Robinson (Alternate)

ON BOARD OF TRUSTEES, UNITED ENGINEERING SOCIETY

H. H. Barnes, Jr., Bancroft Gherardi, H. A. Lardner.

ON ENGINEERING FOUNDATION BOARD

Frank B. Jewett, E. W. Rice, Jr.

ON FRANCO-AMERICAN ENGINEERING COMMITTEE

A. M. Hunt, L. B. Stillwell.

ON JOHN FRITZ MEDAL BOARD OF AWARD

Comfort A. Adams, A. W. Berresford Calvert Townley,
E. W. Rice, Jr.

ON LIBRARY BOARD OF UNITED ENGINEERING SOCIETY

Edward D. Adams, F. L. Hutchinson, Alfred W. Kiddle.
E. B. Craft, W. I. Slichter,

ON NATIONAL FIRE PROTECTION ASSOCIATION, ELECTRICAL COMMITTEE

The chairman of the Institute's Committee on Safety Codes.

ON NATIONAL RESEARCH COUNCIL, ENGINEERING DIVISION

C. A. Adams, Frank B. Jewett, W. R. Whitney.

ON U. S. NATIONAL COMMITTEE OF THE INTERNATIONAL ILLUMINATION COMMISSION

A. E. Kennelly, C. O. Mailloux, Clayton H. Sharp.

WASHINGTON AWARD, COMMISSION OF

John Price Jackson, Charles F. Scott.

U. S. NATIONAL COMMITTEE OF THE INTERNATIONAL ELECTROTECHNICAL COMMISSION

C. O. Mailloux, President, 111 Fifth Ave., New York, N. Y.
*James Burke, Vice-President,
C. H. Sharp, Secretary, 556 E. 80th St., New York.
C. A. Adams, W. C. Fish, L. T. Robinson,
P. G. Agnew, H. W. Fisher, Charles Robbins,
B. A. Behrend, H. M. Hobart, D. B. Rushmore,
J. J. Carty, D. C. Jackson, C. F. Scott,
L. W. Chubb, A. E. Kennelly, C. E. Skinner,
*C. L. Collens, 2d, B. G. Lamme, S. W. Stratton,
W. A. Del Mar, W. S. Moody, Elihu Thomson,
*A. L. Doremus, A. H. Moore, †C. L. Warwick,
Gano Dunn, R. W. E. Moore, R. B. Williamson.
L. F. Morehouse,
*Representative of Electric Power Club.
†Representative of American Society for Testing Materials.

LIST OF SECTIONS

Name	Chairman	Secretary
Akron	H. C. Stephens	R. B. Fisher, 84 Rhodes Ave., Akron, O.
Atlanta	J. E. Mellett	H. N. Pye, Box 1743, Atlanta, Ga.
Baltimore	Douglas Burnett	Vern E. Alden, 1905 Lexington Building, Baltimore, Md.
Boston	Lewis W. Abbott	F. S. Dellenbaugh, M. I. T., Cambridge, Mass.
Chicago	M. M. Fowler	E. H. Bangs, 212 W. Washington St., Chicago, Ill.
Cincinnati	J. D. Lyon	Leo Schirtzinger, 710 Traction Bldg., Cincinnati, O.
Cleveland	I. H. Van Horn	G. B. Schneeberger, Cleveland Elec. Illuminating Co., Cleveland, O.
Connecticut	C. F. Scott	A. E. Knowlton, Dunham Laboratory, Yale University, New Haven, Conn.
Denver	B. C. J. Wheatlake	R. B. Bonney, 603 Wyoming Bldg., Denver, Colo.

Electric Auxiliaries on Merchant Ships

BY E. D. DICKINSON
General Electric Company, Schenectady, N. Y.

WHEN we discuss the Merchant Marine, or any feature thereof, we must not lose sight of the fact that we are dealing with a commercial undertaking which is probably more highly competitive than any other. From its very nature this must be the case, for while each country can make laws to assist the merchant ship owners of that country, every effort to help them and penalize foreign shipping can and undoubtedly will be neutralized by laws of the countries with which they are trading. The only assistance, therefore, that can be given by legislation, outside of providing good port facilities, is to enact laws that will assure a good standard for ships and at the same time not impose penalties in operation to which owners of other countries are not subject.

So we see that the answer to the question, "Who is to carry the merchandise which has to be transported between the various ports of the world?" rests in a great measure with the owners and operators of ships; and because electricity makes possible many reductions in the cost of operation and at the same time enhances the earning power of a ship it is being used to an ever increasing extent for driving the machinery on ships.

On highly efficient new ships, especially motorships, practically all the auxiliaries are driven by electric motors. In the motorship the steam boiler becomes an auxiliary and it is apparent that much of the gain in economy secured by the oil engine would be sacrificed if steam auxiliary machinery were retained. In the steamship, the losses incident to the steam auxiliaries are not so apparent; nevertheless, they are there, a constant drain on the boilers and a continual handicap to any operator or engineer endeavoring to attain efficiency in operation.

It is recognized that a somewhat greater gain in fuel economy is generally secured on a motorship by the adoption of electricity for the reason that Diesel oil engines are employed to drive the generators. Oil engines might be used on steamships with a resultant reduction of fuel required for all purposes. However, there are certain good operating reasons why such an arrangement is not generally popular. It would be necessary to have an engineering force competent to operate and maintain the oil engine. As the pumps essential to the operation of the ship's main engine would be driven electrically, any interruption of the auxiliary oil engine might seriously interfere with the operation of the ship. Fuel oil would have to be suitable for the Diesel engine and in some cases this might necessitate carrying two kinds of fuel oil on ship with the incidental disadvantages. Duplicate equipments for heating, storing and filtering fuel oil would have to be installed. On a steamship, therefore, the most generally accepted practise is to install turbine-driven generator sets for auxiliary power.

At this particular time with the ships of the world tied up owing to lack of cargo, with other countries bending every effort to improve their merchant fleet, and with all men in this country who have the interests of our merchant marine at heart endeavoring to see into the future and maintain such advantage as we have secured due to the large increase in American registry, it would seem that the opportunity afforded by this joint meeting should prove of inestimable value, as engineering advancement can only be secured when a thorough knowledge and understanding of all conditions are recognized by both the manufacturers and users of machinery.

The problem is entirely an economic one. It is only because investigations show that the electrically equipped ship can be operated more economically and can earn more that the question is being discussed. It is the intention of the writer to endeavor to show why this is the case.

Not much information has been published relating to the details of costs of operation of ships. Studies indicate that on new ships electric auxiliaries will show a marked improvement in the economy of operation and will increase the net earning capacity. The future will show that many existing ships can be operated profitably by the substitution of electric for steam auxiliaries. The reasons for expecting such big savings are not at once apparent. Investigations indicate that the losses are partly due to innumerable small leaks and to radiation; in other words, it is the steam

To be presented at the Joint Meeting of the A. I. E. E. and the Society of Naval Architects and Marine Engineers, New York, N. Y., November 17, 1921. Printed in advance to facilitate discussion.

which is generated in the boilers but not put to useful work that in a great measure accounts for the high fuel consumption of many steam-driven ships. When it is recognized that steam is kept on hundreds of feet of piping from the boilers to the steering engine all the time, and in many ships it is always on all deck lines to avoid losses and leaks incident to expansion strains from alternately heating and cooling, and in the winter time there are often considerable extra losses incident to keeping steam on deck machinery to prevent freezing; it can be seen that it is not by any means entirely due to the inefficiency of steam auxiliaries themselves that we get a poor showing, but to the very nature of their application, which cannot be altered. The size of the evaporators fitted in many steamships is proof of the amount of steam that is made by the boilers and passed off into the atmosphere.

Auxiliary machinery on ships can be readily subdivided into two broad types:

(a) for deck use,

(b) for below-deck use.

The motors most suitable are enclosed, weather-proof for above deck, and ventilated for below deck.

It is not the intention to describe a number of different pieces of electric machinery for ships. A study of the technical papers shows an ever increasing amount of space being given to such descriptions. Thoroughly reliable, simple and substantial machinery of various designs has been developed.

Deck Machinery

Deck machinery, properly speaking (that is, all machinery which is exposed to the elements and which must be built with this in view) consists generally of cargo winches, anchor windlass, a certain number of capstans, mooring winches and sometimes special machinery on particular ships. It is true that the steering machinery is not generally exposed to the elements, but is, however, very often housed in an extremely damp compartment. Continuous operation is vital to the safety of the ship. It will be evident that only machinery designed and built for the service should be considered for the application. The service of deck machinery is of an intermittent nature except in some special ships, that is, certain tankers where the motors for driving the cargo pumps are mounted on deck.

Electric deck machinery has been developed along two fundamentally distinct lines: one, in which the motor is mechanically geared to the drums, and the other where some form of hydraulic speed reducing gear is fitted between motor and drum. The latter class seems to have found considerable favor abroad, where certain well-known manufacturers have developed winches using either the Williams-Jenney or Hele-Shaw hydraulic power transmission. Electric hydraulic power transmission is particularly well adapted for steering gear work and has been developed in this country. For general winch service the hydraulic pump and motor are excessively costly. A brief comparison of winches developed abroad and in this country would indicate as follows:

(a) That the speeds for given load are somewhat lower for the foreign-made winch. A drum speed of approximately 175 ft. per minute for 5000 lb. and 250 ft. per minute for 2000 lb. would seem to be good practise.

(b) Certain manufacturers abroad have developed very neat worm-driven winches. These if properly built should be very quiet and from the descriptions appear to be quite compact. The writer does not know of any winches of this type developed in this country. One particular merit of such a winch is that the gear is readily encased, lubricated and protected from the action of the weather.

(c) From several descriptions there appears to be a tendency abroad to operate the motors by contactors. While this arrangement has much merit, it takes up additional space and costs more to install. In one description it is stated that the contactor controller is below deck. This, of course, is possible only in certain cases. Where the winches are located over the cargo holds special space must be provided on deck for the control panels and this space, of course, must be properly enclosed.

(d) There would seem to be a tendency on the part of the foreign winch manufacturers to considerably complicate the motor and control by the addition of special safety devices. In the writer's opinion this will be found undesirable. One manufacturer in this country who has fitted about two hundred electric winches on ships during the past five or six years claims that special safety devices are not only unnecessary but are actually undesirable. For the reason that it must be kept in perfect operating condition at all times so as to function properly when called upon at infrequent intervals, it will be recognized that apparatus for such service is the most difficult of all to maintain. It must be remembered that winches are operated in various parts of the world by longshoremen at the ports and not by the personnel of the ship. Experience indicates that properly designed and substantial equipment is entirely suitable for the service and does not require complicated safety-guarding features.

(e) With the majority of foreign-built winches it would appear that a handwheel is used for operation. This necessitates a tiring and unnatural movement on the part of the winch man. The natural motion and therefore one which can be carried on for hours at a stretch without unduly tiring the operator is similar to working a pump handle, that is, to control by means of a lever raised to raise the load and depressed to lower the load.

For gear winches the series motor or compound-wound with very small amount of shunt winding is

the most desirable. Fig. 1 shows how the natural characteristic of the series motor makes it most suitable for winch service. It is found necessary to throttle the steam winch at light loads to reduce the speed. In practise, therefore, it approaches more nearly the speed of the electric winch. Many winches are fitted with winch heads. When handling cargo with these instead of the drum the rev. per min. will run up somewhat. However, the winch head being of smaller diameter than the drum, it is generally found that the rope speed on the winch head will be about right.

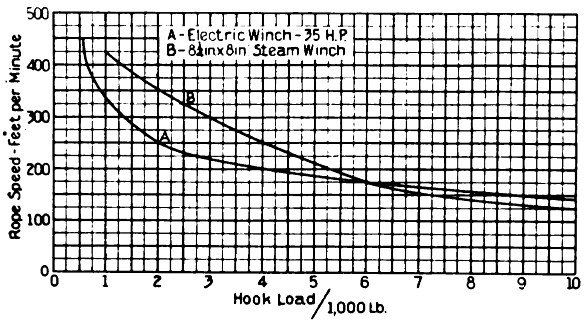

Fig. 1—Characteristic Curves of Electric and Steam Winches

For all service using hydraulic gear, constant-speed motors are used, either alternating-current or direct-current.

Of all the electric apparatus aboard a ship the winch is subject to the most abuse. Everything about it, therefore, should be designed, manufactured, and installed in the most substantial and workmanlike manner.

Specifications for electric deck machinery should cover the following:

1. Insulation should be as highly moisture-resisting as it is possible to get by the use and treatment of the best materials. This applies not only to windings but to all bushings, brush holder collars etc. which if hygroscopic are liable to result in grounds.

2. Motor frames should be thoroughly cleaned and painted on the inside to prevent so far as possible scale forming by corrosion.

3. Covers for inspection openings should preferably be hinged and arranged so as to clamp tightly. On all apparatus, motors, resistor boxes, controllers, etc., if it is impracticable to hinge the covers they should be attached by swinging bolts. Cap screws or cap bolts should not be used as they are liable to be dropped into the motor or left on deck and lost.

4. Bearings should be designed to prevent so far as possible ingress of water and egress of oil due to rolling of the ship.

5. All apparatus should be provided with some form of drain. It must be recognized that while machinery may be built in the factory so water-tight that it can be submerged, there is no assurance that this condition will exist after it has been once opened on deck. Further, any totally enclosed electrical apparatus is liable to breathe under varying temperatures which may result in an accumulation of moisture by condensation.

The cost of good electrically fitted machinery installed should be little, if any, more than that of high-grade steam machinery. Of course, until apparatus reaches a stage of standardized production the costs cannot be materially reduced. It must be remembered that while in steam machinery all kinds of economies may be practised at the cost of quality, in electrical apparatus built to withstand marine conditions and severe service a departure from the highest grade is most certain to be followed by failure and consequent cost to the operator. The making and insulating of electrical machinery cannot be materially hastened, as the successive dryings or bakings of the insulation must be given proper time—otherwise, it may be imperfect. The insulation in a marine motor must be moisture-resisting to the maximum practical extent—otherwise, it should not be deemed proper for the service.

Fig. 2 shows a deck winch developed in this country, several of which type will shortly be installed on ships. This winch is a radical departure from the generally recognized designs using either spur or worm gearing.

Electric steering gears have been developed for mechanical control of the rudder. For these the service is extremely intermittent, operating from two to ten times per minute, which means that the motor would be started, stopped and reversed thousands of times during one voyage. Such gears require the installation of a motor of sufficient torque to swing the rudder to the extreme angle, whereas during most of the time a very small amount of power is required. This means loss in efficiency as the motor is operating nearly all the time very much underloaded.

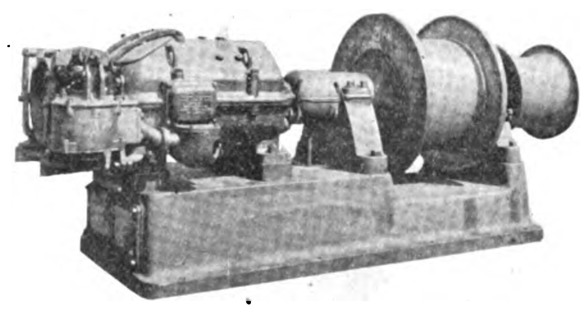

Fig. 2—New Type of Electric Cargo Winch Having the Reduction Gear Inside the Drum

For controlling the steering gear from the pilot house two electrical means are available, follow-up and non-follow-up. The first entails considerably more wiring, a multiple switch in the wheel house, a more complicated control in the steering engine compartment, and has the disadvantage of moving the rudder step by step a definite number of degrees. By the non-follow-up means the rudder can be moved by fractions of degrees in either direction; its use, however, calls

for the installation of a rudder indicator in the wheel house. A device has been worked out to show positively the position of the rudder at any instant, using simple means already developed.

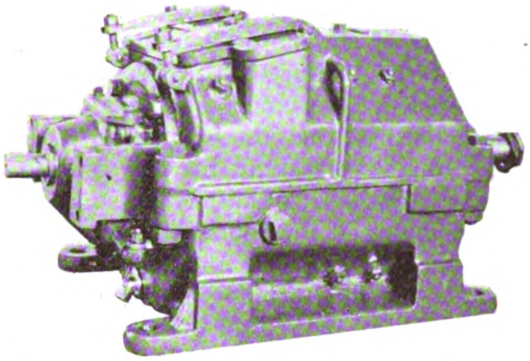

Fig. 3—Marine D-C. Motor—Enclosed, for Operating Deck Machinery

Special Deck Machinery. There are many special applications of electricity to machinery for shipboard not normally included as part of the regular equipment of a cargo ship wherein the use of electricity is particularly well suited. By the proper application of principles already worked out, it will be found that towing engines, mooring winches and other special pieces of machinery can be built to operate electrically in a very simple manner and with as great, or greater, reliability than steam machinery already developed.

The following is a table of deck machinery which with slight modification would be applicable to ships

Fig. 4—Marine Controller for Deck Machinery Motors

of any tonnage between 8000 and 10,000 tons dead weight. It should be borne in mind that the size of the cargo winches is based upon the best practise for general cargo and therefore does not vary greatly with the size of the ship. The number of winches, however, has to be modified to suit the number of hatches and derrick booms of the different ships.

	No. units	Assumed motor h. p.	Duty
Anchor Windlass	1	70	Very intermittent, severe Often submerged May be stalled in operation
Cargo Winches	12	35	Intermittent Fast cycle, severe duty Sometimes submerged Wide range in loads and speeds
Steering Gear	1	35	Seldom fully loaded Severe intermittent duty with mechanical gear Moderate continuous duty with hydraulic gear

TYPES DEVELOPED (ELECTRIC DECK MACHINERY)

	Drive	Motor	Speed Control
Anchor Windlass and Capstan	Spur-gear Worm-gear	Reversing	Electric
	Hydraulic	Constant-speed	Hydraulic
Cargo Winch		Reversing	Electric with electric brake (general use)
		"	Electric with mechanical brake
	Worm-gear	Constant-speed	Mechanical brake and clutch (free drum winch)
	Spur-gear	" "	Mechanical brake hoisting and lowering clutches
		" "	Reverse gear and brake
		" "	No speed control (winch head only)
	Hydraulic	Constant-speed	Hydraulic
Steering Gear	Spur-gear	Reversing	Electric Remote
	Worm-gear	"	" "
	Hydraulic	Constant-speed	Hydraulic "

Below-Deck Machinery

It should not be necessary to emphasize the importance of fitting equipment of proper design and of the highest grade material, particularly pumps vital to the operation of the ship and which must be relied upon to operate continuously day and night for weeks at a stretch.

The greater part of the electrical machinery below deck is naturally located in the engine room. The following table gives a list of below-deck auxiliaries suitable for a cargo ship of about 8000 to 10,000 dead weight tons and equipped with 2500 to 3000 shaft-h. p. steam turbine. A motorship requires somewhat fewer auxiliaries, and slightly less power is necessary for driving them. Tankers require a number of motor-driven pumps for discharging the cargo. These may be installed either in a special pump room or arranged with the motors on deck with vertical

shafts to the pumps below. It will be noted that in the list there are only five sizes of motors. That is with the intent of simplification and to reduce the number of spare parts to be carried. A study of particular cases may show that it is possible to arrange satisfactorily the engine room equipment so as to have still fewer sizes.

BELOW-DECK AUXILIARIES

	No. units	Assumed motor rating in h. p.	Duty
Propulsion			
1. Circulating pump	1	40	Continuous at sea
2. Boiler feed	2	25	One continuous at sea
3. Forced draft fan	1	20	Continuous at sea
4. Condensate	1	5	Continuous at sea
5. Lubricating oil	2	5	One continuous at sea
6. Oil cooler water	1	5	Continuous at sea
7. Fuel oil	2	5	One continuous at sea
8. Fuel oil trans.	1	5	Intermittent (assume 4 hr. per day
Service			
9. Fire and bilge	1	10	Intermittent (assume 6 hr. per day
10. General service	1	10	Intermittent (assume 6 hr. per day
11. Sanitary	1	5	Intermittent (assume 12 hr. per day
12. Fresh water	1	5	Intermittent (assume 2 hr. per day
13. Refrigerating	2	5	One continuous at sea
14. Evaporator	1	5	Intermittent (assume 3 hr. per day
15. Ballast	1	10	Intermittent (assume 4 hr. per day
16. Work shop	1	5	
17. Oil purifier	1	5	
18. Galley	1	5	

Motors for these auxiliaries should be designed for continuous running, because while certain pumps may be started and stopped frequently, the service cannot be considered intermittent.

In the engine room, and in fact even if placed in the lowest part of the ship, totally enclosed motors are not recommended. For continuous operation they would have to be excessively large. With the changes in the atmosphere that take place below the water line, enclosed motors would be more liable to sweat and accumulate moisture internally than if well ventilated. In general, enclosed self-ventilated motors are recommended for the reason that they are often located in congested places, where if open they would be liable to mechanical injury and in addition would have to be protected from dripping water. However, as electrical machinery when open is more readily inspected and kept clean, it is not essential that the motors be enclosed if located, *e. g.*, on a gallery and properly protected from dripping water. Such motors should be screened to prevent rats eating the insulation. On tankers, if the cargo pump motors are of the direct-current type and are located in a special pump room, they must be provided with some means of ventilation which will insure all explosive gases being driven off before the motors are started.

The motors in the engine room should be insulated with the same care and the castings as thoroughly cleaned and painted as the motors on deck. The insulation on all marine electrical apparatus should be made as highly moisture-resisting as possible.

As illustrating the adaptability of electrical apparatus, the writer recently saw a report from a chief engineer which stated that when the steam engines on his circulating pump and dry vacuum pump broke down he replaced them by two deck winch motors. The drive was so satisfactory that he intended to recommend that it be made permanent and incidentally the ship burned $1\frac{1}{2}$ tons of fuel oil per day less after the change.

Control. It would seem desirable that the means for starting and stopping each motor be located directly

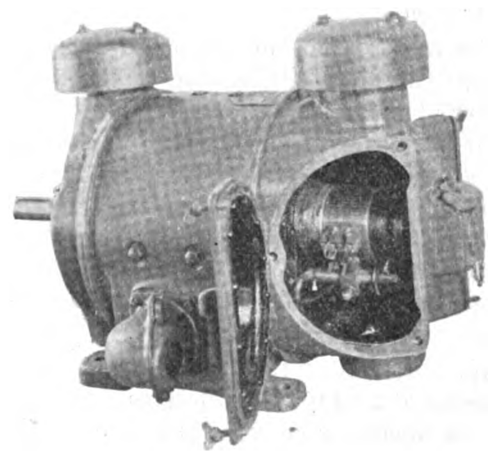

FIG. 5—MARINE D-C. MOTOR—ENCLOSED, VENTILATED, FOR OPERATING BELOW—DECK MACHINERY

adjacent to it. Such starters are relatively inexpensive. They should be very substantial and moisture-resisting. Thin sheet iron should not be used, especially on any part of the construction which cannot be readily painted, as after a short time it is liable to rust and may be the cause of serious trouble.

On steamships the motors on the circulating pump, lubricating oil pump, boiler feed pump, hot well pump, balancer set or lighting motor-generator set if any, and steering gear, should be fitted with starters so that when power is restored after an interruption these particular motors will immediately start up automatically. The other motors can be restarted by the engineer at his convenience.

Generating Units. A study of the installations on a number of cargo ships of various tonnages indicates that on a steamship 150 kw. would give ample power for the deck machinery when in port and for the entire engine room equipment when at sea. On a motorship about 75 kw. is necessary at sea. Therefore, on cargo ships of about 10,000 dead-weight tons, two 150-kw. steam turbines or on the motorships three

75-kw. generator sets would give ample power with one unit for a standby at all times. The auxiliary power in many cases will be much greater than 150 kw. *e. g.*, refrigerator ships and ships fitted in part for passenger service. The larger the amount of auxiliary power the greater the reason for highly efficient auxiliary turbines. Some studies have shown requirements for auxiliary power as great as 1500 kw.

Small steam turbines should be substantial and simple as they will be classed as part of the propelling machinery and therefore vital to the safety of a ship. In sizes of 150 kw. and even smaller, gear reduction would be recommended, as the best direct-current generator operation cannot be expected at the speed at which the turbine should run in order to get good economy. It is expected that these sets would be more substantial and conservative than sets of similar capacity for land service where they are at all times readily accessible.

For the reason that on shipboard there is always possibility of scale or salt passing to the turbine from the boilers it is preferable for the governor to control the speed by means of an oil Servo motor. All parts should be readily accessible. Even with the greatest care there is always liability that the lubrication may be momentarily interrupted, and as the bearings should be examined before the machinery is placed in service they should all be readily removable for inspection. An overspeed or emergency governor of the simplest and most reliable type should be fitted. Very specific and simple instructions should be issued to show the operating engineer the necessity of testing the governing mechanism periodically and assuring himself that it is in perfect operating condition.

THE MOST SUITABLE ELECTRIC POWER.

All references indicate that at the present time direct current is being generally adopted for auxiliary power on merchant ships. Some time ago there was considerable discussion as to the relative merits of alternating current and direct current. The following tabulation will show why direct current is being used to the greater extent:

CARGO SHIPS

DIRECT CURRENT

Arguments for	Arguments against
1. Simple wiring.	1. Commutators require some attention.
2. Any speed control easily obtained.	
3. Equally suitable for continuous and intermittent duty.	

ALTERNATING CURRENT

1. Lower cost of motors and generators.	1. Wiring more expensive.
2. Absence of commutators.	2. Unsuitable for variable speeds necessitating hydraulic or other gear for winches and windlasses.

TANKERS

DIRECT CURRENT

1. Simple wiring.	1. Commutators require some attention.
2. Equally suitable for continuous and intermittent duty.	2. Little necessity for variable-speed motors. Special cases could be fitted with hydraulic or direct-current power furnished from small motor-generator set.
3. Speed of cargo pump can be varied to suit pressures and most efficient rate.	3. Special precautions must be taken to ventilate motors in tank room.

ALTERNATING CURRENT

1. Lower cost of motors and generators.	1. Wiring more expensive.
2. Absence of commutators, particularly desirable in pump room.	2. Special motors necessary to change speed.
3. Cargo handled by constant speed pumps.	

It would seem that for cargo ships direct current can be used to the greatest advantage. On tankers this is not so apparent.

Except in the smaller ships, it is desirable to use not less than 230 volts. The lower voltage necessitates large or more expensive control; also the cost of wiring and switches is greater.

For lighting, the arguments seem to be in favor of 115 volts. This necessitates the installation of a small 115/230-volt motor-generator set. The use of incandescent lamps for 230 volts is not recommended. They are of necessity built with a very fine filament, and are, therefore, less substantial and further are not easily procured in seaports.

WIRING AND INSTALLATION

It is impossible to speak too forcibly on this subject. A great deal of critcism of electrical apparatus when thoroughly investigated has been found to be directly due to faulty, careless, slipshod methods of wiring and installation. Care and attention have been given to choosing apparatus, but the method of installation, the kind of wire, and many details of vital importance have been left to the wiremen's discretion with the inevitable result.

It is not the intention here to suggest that definite rules be laid down. Each engineer must work out his own particular problems. Certain underlying fundamentals, however, can generally be applied. The following are recommended:

That the wiring and distribution in the engine room be made as simple as possible, with relatively few circuits.

The switchboard should be largely a distribution panel designed with the idea of attaining maximum simplicity and occupying the least amount of engine-room space.

Circuits may be led from this distribution panel to different parts of the ship where they may be further subdivided, as *e. g.*, five circuits for deck machinery No. 1 to the steering engine, No. 2 to the after hatches No. 3 to the forward hatches, No. 4 to anchor windlasses,

and forward capstans, No. 5 to after capstans. This will permit opening all the winch circuits when at sea and also allow for thorough inspection and try out of the capstans, anchor windlass or steering engine when in port even if cargo is being handled.

In the engine room, a similar method may be applied, one circuit to the engine room auxiliaries, port side and another to the starboard side. By such simplification it will be possible to obtain low cost with maximum reliability.

Cables should not be run in conduits except perhaps for very short lengths where necessary for mechanical protection. Cables in the engine room should be run overhead. All cables should be thoroughly anchored so that the covering will not be chafed due to vibration.

Operation

To study the relative merits of ship's auxiliaries, it is necessary to consider the part which they play in the economic operation of the ship.

For certain special types of ships designed and built to operate for some particular service, such as tankers and lake ore carriers, it is not difficult to show definitely why a certain installation will give the best return on the investment.

In the cargo ship, however, the problem is not so clearly cut. While it is true that a certain number of ships may be designed with the intention of travelling particular trade routes and handling a special cargo it is often found that their schedule must be modified. Therefore, the general cargo ship must be built to handle all kinds of cargo and at best, therefore, the apparatus with which it is equipped is somewhat of a compromise.

It is not possible to make any exact general statement as to the proportions of the various items constituting the cost of operating merchant ships. They may, however be listed as follows:

1. Fuel and lubricating oil at sea and in port.
2. Port charges including wharfage, lighterage, pilot fees, canal dues, stevedoring, tug-boat charges, etc.
3. Salaries and subsistence.
4. Up-keep and repairs, deck department.
5. Up-keep and repairs, engine department.
6. Supplies, engine, deck and steward's departments.
7. Insurance.
8. Loss and damage.

If we assume a 7800-dead-weight ton ship fitted with 2500-h. p. steam turbine on a schedule for coastwise service between New York and Seattle, stopping at San Pedro to load and discharge cargo and making four round trips per year, the charges might be approximately as follows:

OPERATING DISBURSEMENTS

	Loaded both ways	Percentage	Loaded going one-half loaded returning
1. Fuel	$81,300	14.8	$81,300
2. Port charge	290,420	52.9	211,020
3. Salaries	60,490	11.0	60,490
4. Repairs, deck	10,000	1.8	10,000
5. Repairs, engine	20,000	3.7	20,000
6. Supplies	20,250	3.7	20,250
7. Insurance	62,400	11.4	62,400
8. Loss and damage	3,650	.7	3,650
Total	$548,510	100%	$469,110

Many of these would be affected by electrification of auxiliaries, and the net reduction would be very considerable.

1. *Fuel, etc.* In the usual marine geared turbine installation with steam auxiliaries, the pressures generally carried are as follows:

Boiler pressure	210 lb. gage
Turbine bowl	200 lb. "
Auxiliary steam line	100 lb. "
Auxiliary exhaust	10 lb. "
Superheat	75 deg. fahr

The auxiliary exhaust steam is used to heat the feed water and that which is in excess of feed-water heater requirements is by-passed to the main condenser.

Under full power, a fair operating average for this type of installation is as follows:

Steam consumption per hour:

Main turbine, 2500-h. p.	28875 lb.
Steam auxiliaries at sea	12500 "
Total steam consumption	41375 "

Steam per shaft horse power hour, all purposes:

$$\text{Steam per shaft h.p-hr., all purposes} \ldots \frac{41{,}375}{2500} = 16.5 \text{ lb.}$$

Boiler Evaporation:

With water-tube boilers, Howden draft system, feed water delivered to boilers at 220 deg., 210-lb. gage pressure and 75 deg. superheat, a conservative estimate of the actual evaporation per pound of fuel oil is taken at 13.5 lb.

Fuel Consumption:

$$\text{Fuel per hour} = \frac{41{,}375}{13.5} = 3065 \text{ lb.} \ldots = 9.6 \text{ bbl.}$$

Fuel per day ....73,560 lb. .... = 32.8 tons
Fuel in bbl. per day 230

Fuel per shaft horse power hour:

$$\text{Fuel per shaft horse power hour} = \frac{3065}{2500} = 1.23 \text{ lb.}$$

Fuel in barrels, per knot:

$$\text{Assuming a speed of 10.5 knots } \frac{9.6}{10.5} = 0.915 \text{ bbl. per knot}$$

The economy to be gained through the application of electrically driven auxiliary machinery, in fuel consumption alone, may readily be seen from the following estimates.

ELECTRIC AUXILIARIES

SUPERHEAT 75 DEG. FAHR.

Heating feed water:

The proposed method would be to extract sufficient steam from the turbine for feed water heater requirements.

Steam consumption, per hour:

Main turbine 2500-h. p.	30,600 lb.
Turbine generator	2,640 "
Air ejector	1,000 "
Total	34,240 lb.

Note: 3600 lb. per hour steam will be extracted from main turbine at about 10 lb. gage to heat feed water.

Steam per shaft horse power, all purposes:

$$\text{Steam per shaft h.p-hr., all purposes,} \quad \frac{34{,}240}{2500} = 13.7 \text{ lb.}$$

Boiler Evaporation:

Estimated for comparative purposes at 13.5 lb. per lb. of fuel. With the lesser quantity of steam to generate, however, the boiler efficiency would be improved in actual practise.

Fuel consumption:

$$\text{Fuel per hour } \frac{34{,}240}{13.5} = 2536 \text{ lb.} = 7.9 \text{ bbl.}$$

Fuel per day 60864 lb. = 27 tons
Fuel per day in bbl. = 189 bbl.

Fuel per shaft horse power hour:

$$\text{Fuel per shaft h.p-hr.} = \frac{2536}{2500} = 1.01 \text{ lb.}$$

Fuel in barrels per knot:

$$\text{Assuming a speed of 10.5 knots, } \frac{7.9}{10.5} = 0.75 \text{ bbl. per knot.}$$

The application of high superheat, well within the limits of present-day design, and electric auxiliaries present a very interesting and high economic value in ship propulsion.

ELECTRIC AUXILIARIES

SUPERHEAT 200 DEG. FAHR.

Steam consumption, per hour:

Main turbine, 2500 h. p.	27,000
Turbine generator	2,400
Air ejector	1,000
	30,400

Note: 3000 lb. per hour steam will be extracted from main turbine at about 10 lb. gage to heat feed water.

Steam per shaft horse power, hour all purposes:

$$\text{Steam per shaft h.p-hr., all purposes} \ \ldots\ldots \frac{30{,}400}{2500} = 12.15$$

Boiler evaporation:

Assumed at 13 lb. per pound of fuel.

Fuel consumption:

$$\text{Fuel per hour} = \frac{30{,}400}{13} = 2340 \text{ lb.} = 7.33 \text{ bbl.}$$

Fuel per day 56,200 lb. ..... = 25.1 tons
Fuel in bbl. per day .... = 176 bbl.

Fuel per shaft horse power hour:

$$\text{Fuel per shaft h.p-hr.} = \frac{2340}{2500} = 0.936 \text{ lb.}$$

Fuel in barrels per knot:

$$\text{Assuming a speed of 10.5 knots } \frac{7.33}{10.5} = 0.698 \text{ bbl. per knot.}$$

These estimates show the saving in fuel consumption by the use of electric auxiliaries, as follows:

Saving in Fuel Consumption (at sea):

Steam auxiliaries	230 bbl.	
Electric "	189 "	17.3 per cent
Electric " with 200 deg. fahr. superheat	176 "	23.5 per cent

Saving per year:

208 days at sea, oil at $1.50 per bbl.

Electric auxiliaries	8320 bbl.	at $1.50	$12,480
Electric " with 200 deg. fahr. superheat	11,250 "	" $1.50	16,900

In the estimate, an allowance was made of 40 bbl. per day in port. With electric auxiliaries, and economic engine room machinery, it should be possible to reduce this by one-half.

157 days × 20 lb. × $1.50 .... = $4,710

With a good system in the engine room, the lubricating oil required would be greatly reduced.

2. *Port Charges.* In giving thoughtful consideration to improving the earning power of a ship, it will be recognized as essential to decrease its idle time, as certain charges are continuous, whereas the ship is actually earning money only when traveling between ports. When it is realized that the average cargo ship makes only about 36,000 miles per year and that at an average speed of 10 knots, this means she is at sea only about 150 days out of a year, it is very evident that there is a big field for improvement.

Port charges estimated for the coastwise schedule mentioned above are as follows:

	N. Y.	Colon	Los Angeles	San Francisco	Seattle	Total
(a) Wharfage	$7800	....	$1560	$3120	$3120	$15,600
(b) Lighterage	....	....	....	....	....	....
(c) Pilots fees	202.56	....	200	250	....	652.56
(d) Stevedoring	7800	....	1560	3120	3120	15,600
(e) Tug-boat charges	100	....	....	200	....	300
(f) Canal dues	....	$4150	....	....	....	4,150
Total per trip						$36,302.56
Total per year (4 round trips)						$290,420.48

It will be evident that any means which will reduce the time a ship has to lie at the wharf loading or unloading cargo should lessen the two items *wharfage* and *stevedoring*. The writer has been informed of specific cases where ships have been delayed at docks due to freezing of steam deck machinery. He has also been informer of a specific case where two similar ships loading and unloading the same kind of cargo at the same dock and with the same stevedore foreman, the electrically equipped ship loaded in very much less time. Another specific case where a number of ships fitted with steam deck machinery had to await a derrick to assist in loading heavy cargo, where a ship fitted with electric machinery was able to handle its own cargo and saved a number of days delay.

Delays have been experienced with steam machinery due to low steam pressure. This may not be due to drop in boiler pressure but to loss in piping. With electric equipment, there is always ample power available for the winches.

By the use of the most suitable electric machinery, it should be possible to reduce the item of port charges 10 per cent. In the estimate given above this would mean approximately $30,000 per year saving.

3. *Salaries.* In all probability the salaries would not be directly affected. In the larger ships and in those where there is a very large amount of auxiliary power it might be found desirable to increase the salary slightly for one of the positions, in order to secure a man with electrical experience.

4. and 5. *Upkeep and Repairs.* Both of these items should be reduced. With properly designed electric machinery, the charges for repairs and maintenance would be less than with steam machinery. If compared with many existing ships a 20 per cent reduction would in all probability be a conservative estimate. If we only allow 10 per cent, however, this would mean a saving of approximately $3000 per year on the above estimate.

6. *Supplies.* This item would not be appreciably affected in the deck department, but for the engine department, there should be a material reduction.

A saving of 10 per cent might be expected, which would amount to $2000 per year.

7. *Insurance.* The assured reliability of proper electrical machinery in the engine room, along with the elimination of a large amount of piping carrying high-pressure steam, should have a direct bearing on the insurance rate. Indirectly, by reducing the loss of steam it should be possible to maintain the water in the boilers in almost perfect condition. This should still further add to the safety of a ship. It would seem to be justifiable to expect that the insurance premiums can be decreased about 5 per cent; this would mean a saving of approximately $3000 per year.

8. *Loss and Damage.* This item in all probability would not be affected.

The sum of the different gains mentioned above totals $55,190 per year. The amount of saving that can be shown by other estimates will naturally vary with conditions. In any estimates the possibility of making a substantial gain in the earning capacity in a ship is a real one. Having in mind certain ships, there is every reason to believe that the figures mentioned above might be increased.

One of the latest British combined cargo and passenger ships is equipped electrically and is fitted with over 100 motors driving auxiliary apparatus. Needless to say, the owners of new foreign ships are fitting them with electrically driven machinery only because they have satisfied themselves that it is profitable to do so. We engineers in this country should combine our efforts and avail ourselves of every opportunity to improve the efficiency of our merchant ships to the end that they may be able to compete successfully with the modern ships being placed in service by the other counties.

HYDROELECTRIC PROJECT FOR SOUTH CAROLINA

The Federal Power Commission has just issued for a period of two years, a preliminary permit to the Columbia Railway and Navigation Company of Columbia, South Carolina, which secures to it priority of application for a license for a navigable canal twenty-four miles long and not less than ten feet deep which will extend in a southeasterly direction from a point near Ferguson on the Santee River to the headwaters of the Cooper River. It is proposed to build a hydroelectric plant at the southerly terminus of the canal where a head of about 30 feet can be obtained. It is estimated that about 4000 h. p. of continuous power will be available while the secondary power available will perhaps amount to three times as much.

The proposed project contemplates the diversion of water from Santee River, which is navigable in its lower reaches, to Cooper River. The diversion of a large amount of water during low-water stages may have a detrimental effect on navigation on the Santee River. In order to protect the interests of navigation, the permit provides that surveys of the river shall be made and stream-discharge data collected, in order that the permissible diversion may be determined.

A study will be made of the effect that restrictions on the diversion of water from the Santee River will have on the economic operation of the power plant. Studies of the possibilities of storing water along the route of the proposed canal, of the extent to which Cooper River Valley will be flooded because of diversion of water into it, and of the silting of Charleston Harbor will also be made.

ELECTROLYSIS REPORT

During the past month the report of the American Committee on Electrolysis has been completed and it will soon be printed. This work will bring up to date the conclusions and recommendations that have been agreed upon as a result of a joint study of the electrolysis problem by the Bureau of Standards and the utility interests represented on the American Committee on Electrolysis.

During the month also the final experimental field trials of the earth current meter have been completed and the completion of these field trials has definitely established the utility of this instrument for practical electrolysis survey work. Plans are now being made to use several of these instruments in connection with the cooperative work of the Bureau and the Research Subcommittee of the American Committee on Electrolysis.

Gathering In Coal Mines

BY R. L. KINGSLAND

Consolidation Coal Company, Inc., Fairmont, W. Va.

IT was evidently the intention of your Committee that this paper should deal principally with a comparison of costs for different methods of gathering. One case, cited from records of the Consolidation Coal Company, will show that such comparisons are hardly practical. During 1916 coal was gathered for 5 cents per car. During 1920 coal was gathered with the same locomotive, from the same mines, and under mining conditions more favorable to the locomotives, for 20 cents per car. This increase is accounted for by large labor increase, poor and irregular railroad car supply, and decrease in efficiency of labor.

The above case shows the wide variation in costs due to changing conditions other than mining conditions. The different conditions encountered in different mines may give as wide variation in costs as the one above.

As costs for the past few years have not been comparable, and also as I do not have sufficient comparable figures for different methods of gathering under similar conditions for any one period, it will be necessary to confine this paper to a discussion of the different methods available for gathering coal and a short discussion of the limitations of each.

The simplest form of gathering is where the miners themselves push the cars into and out of the rooms. Obviously this method has great limitations, but it is still being employed in some places where the grades are in favor of the loads and where small cars are used.

Horses or mules probably still gather the greatest part of coal mined in the bituminous fields. Our experience has shown that a fair average for live stock gathering is two and one-half cars per hour or twenty cars for an eight-hour day.

We now come to mechanical gathering. This is a comparatively new field and I believe should be approached by the average mine operator with considerable caution. It is the writer's opinion that the cases where a decrease in gathering cost can be made, due to changing from live stock to mechanical gathering, are the exception, rather than the general rule. By this I do not mean to say that mechanical gathering does not have an important part to play in the coal mining of today. There are other reasons, aside from costs, which will justify replacing stock gathering with mechanical gathering: Such as, scarcity of labor, the attitude of labor against pushing any cars, and the fact that increased tonnage can be had from some mines due to less congestion in traffic with mechanical gathering.

Presented at the combined meeting of the Pittsburgh Sections of the A. I. E. E. and A. I. M. E., Pittsburgh, Pa., January 21, 1921.

The only power that we have used for gathering locomotives has been electric power, so I limit myself to electrically driven locomotives. Of these there are three principal types: Crab reel, cable reel, and storage battery locomotives. We have found that good results could not be obtained from the straight crab reel locomotive due to the excessive amount of labor required in pulling the cable into the rooms. Also this type of locomotive is not suited to pushing empty cars into the room. We have found, however, that in some mines, crab reels on part of our locomotives are very handy for odd jobs.

Cable reel locomotives, we consider as one of the most adaptable types for gathering. These locomotives are very flexible and have been successfully run with some very long cables. The principal trouble that we know of with them, is cable trouble. Inexperienced motormen will run over their cable frequently and cause considerable delay.

The third principal type is the straight storage battery locomotive. This locomotive has maximum flexibility as it can run anywhere, irrespective of feed lines and return lines, on its own power. There are, however, several limitations to the battery locomotive. It is limited in its day's work by the size of battery and the corresponding amount of energy which can be stored in same. Due to the weight of the battery, the locomotive can be abused by pulling too large trips, under which condition the battery energy will be expanded before the end of the day. The batteries require expert and systematic attention.

Our company has had considerable experience with combination trolley and storage battery locomotives. About 50 of these have been installed in one of our divisions. These are standard 250-volt, two-motor, six-ton locomotives, of the type usually used with cable reels. We have dispensed with cable reels and provided the locomotives with storage batteries in their place. The batteries receive boosting charges throughout the day, whenever the locomotives are running on trolley. The special field for this locomotive is where the mining work is scattered. The locomotive can gather a few cars in one place on the battery, and then run, on the trolley, to some other section for a few more cars. In comparison with the reel locomotives our mine people claim that it has extra flexibility. In comparison with the straight storage battery locomotives it has a much wider range of operation, due to its high speed on the trolley and the extra drawbar pull, which it is capable of exerting while on the trolley.

No mention has been made so far of room hoists. We have found it necessary to use these in some parts of our mines where the grades are too heavy for loco-

motives. As a general rule I would say that grades averaging 15 per cent are about as steep as can be successfully met with locomotives. We, of course, realize that locomotives have been, and are being, used on grades considerable in excess of this. The maximum grade on which I have seen a locomotive operate was 25 per cent.

The big question for the mining man is to know what type of locomotive to apply to the individual mine which he has under consideration. There are some mines where this question is very simple, but the majority of them will permit the installation of two or more types of locomotives and it is extremely difficult to determine which type will give the maximum results.

Let us assume as an average condition a mine that is at present gathering with live stock. The chances are that the mine will be developed so that in the majority of cases the grades will be in favor of the load. Part of the empty cars are delivered to the face with live stock and probably part of them are pushed from the room necks to the face by men. Also part of the loads are pulled from the face with live stock and the remainder are dropped from the face to the room necks by the men. In practically all cases the loads are not taken farther than the end of the room entry by the live stock. In most cases rooms are driven only one way from the room entry, and there are probably not more than six or eight rooms being worked on each entry. Under these conditions the live stock will average about 20 cars a day per head. In changing over to mechanical gathering, in order to make a favorable showing it would be necessary for each locomotive to replace four head of live stock. This would mean that two men with one locomotive would do the work of four men with four head of stock. It should be understood from the beginning that this result cannot be accomplished unless changes are made in the method of mining and condition of mine tracks. We have found in all cases where this change in the method of gathering has been made that it is necessary to improve materially track conditions so as to prevent derailment. Also the development work in the mines should be laid out so that each locomotive can get its full quota of loads from one room entry if possible, and in no case more than two room entries. Another important point is to avoid increasing the length of haul from the working faces to the side tracks in changing the gathering system. The tendency with most mine superintendents is to believe that the gathering locomotives should be able to haul farther than the stock, and they therefore expect them not only to gather as much as four head of stock but to haul these cars a greater distance to a side track than the live stock had previously done. All of the points mentioned above seem simple, but we have found by experience that they are quite important.

We will now turn to the special application of different types of locomotives. One undisputed field for the straight storage battery locomotive is in gaseous mines where no other type of locomotive is permissible. On the other hand, where heavy grades against the loads are encountered, the straight storage battery locomotive is not practical, as sufficient energy cannot be stored in it for the day's work. Between these two limitations there is left by far the biggest field where the different types of gathering locomotives meet on nearly equal grounds. Before leaving the battery locomotive I strongly advise against the installation of any such type of locomotives unless a sufficient number of them are installed so that they are accessible enough for a trained battery man to give each one regular and systematic inspection. Under general conditions I do not believe that it is advisable for an isolated mine to install one or two battery locomotives, unless it happens to have a man familiar with such equipment who will give them the necessary supervision. My strongest argument in support of this recommendation is the fact that we have been able to operate lead batteries in combination locomotives under the above recommended plan so that we have secured an average of about 50 per cent more than the guaranteed life on same. It should be noted that the service in combination locomotives is even more severe than that in straight storage battery locomotives, in so far as the batteries are concerned. This is due to the fact that in straight storage battery locomotives there are only one charge and one discharge per shift, while with combination locomotives the battery starts the day fully charged and is given boosting charges at frequent intervals throughout the day. This probably averages the equal of at least two full charges and two full discharges per shift, or twice the service demanded from straight battery locomotives.

In the case of a new mine that will be developed so that the work will be concentrated and each locomotive can get its full quota of coal from one or two room entries, and where the grades are not prohibitive, I would recommend the straight storage battery locomotive as being best suited for the work.

We still have left the majority of applications for gathering locomotives; that is, for operating mines that wish to install mechanical gathering. We have only eliminated from these mines, those that are gaseous, and those that have grades averaging 15 per cent or more. For the remaining mines consider that the straight storage battery locomotive has the smallest application. It should be applied to mines where the work is already concentrated, to those where the large part of the work will be concentrated within a short time, and to those where the maximum average grade is under 5 per cent.

There are now left the reel and the combination locomotives. I would recommend the reel locomotive for maximum average grades up to 15 per cent, and

the combination locomotive for maximum average grades up to 10 per cent. The latter limitation is made on account of the limited energy storage capacity of the storage battery. We have already given limitations which recommend against the use of storage batteries unless a sufficient number of them are installed close enough together for one battery man to keep close track of their care and operation. For the cases where there are not enough batteries to justify the services of one man for their care, I would recommend the cable reel locomotives. For the cases where there are a sufficient number of locomotives to justify the services of a battery man, I would recommend the combination locomotives. This recommendation is based on experience with both types of locomotives. The combination locomotives have been found more flexible, due to their lower speed and closer speed regulation when running from the battery. The battery should give about 125 volts while the reels have full trolley voltage of 250 or 500 volts. Also experience has shown that there are less delays due to batteries and accessories than due to cable reels and accessories. A locomotive with cable reels costs less than the same locomotive with storage batteries. I have found that the maintenance cost on one is about the same as that on the other. There is probably some small difference in power consumption of the two types. We have not made any accurate tests on this, because general results show that there is no appreciable difference. Our records show that the combination locomotive will gather from three to five cars more than the reel type per day, and we consider that this increase more than makes up for the extra investment necessary for the combination trolley and storage battery locomotive.

So far no mention has been made of mechanical gathering other than locomotive gathering and room hoists. Numerous systems of conveyers and scraper loaders have been suggested, but to date we have not found any that we could apply to our systems of mining so as to show a saving over locomotive gathering, nor have we seen our way clear to change our systems so as to suit any of the methods suggested.

When considering mechanical gathering for a mine, too much emphasis cannot be placed on the necessity of making mining conditions suitable for such gathering. For a new mine, where mechanical gathering will be used from the start, this should cause but little extra expense. For an old mine where live stock has been used extreme care must be taken in selecting the best method of mechanical gathering for the individual mine, all tracks must be put in good shape, the feed lines and returns must be ample for the service and ample side tracks must be provided as close as practical to the working faces. Also the more the mine workings are concentrated the better will be the results with mechanical gathering. Unless all of these things are watched closely the cost of mechanical gathering will show an increase over live stock gathering. With mechanical gathering the weight of locomotive can be suited to the weight of the cars. Under given conditions a locomotive should gather a certain number of cars per day. The larger the cars the larger the locomotive, but the number of cars gathered per day remains practically constant. Obviously the larger the car the cheaper the gathering cost per ton of coal mined.

TELEPHONE PROGRESS IN CHINA

A movement has been inaugurated to hunt up all the principal cities of China by long-distance telephone toll lines. This movement started with the business men of northern China who realize that little progress will be made in the unification of the country until modern methods of communication are adopted. The telephone is especially adapted to conditions in China, because the use of the telegraph is beset with many difficulties on account of the many characters in the Chinese alphabet which make it necessary to send all messages in code.

It is reported by Mr. Clark H. Minor, former Manager of the China Electric Co., of Pekin, who has just arrived in New York, that work has already begun on a long distance line between Shanghai and Peking that will connect with the toll system now in operation between the northern capital and Tietsin. The latter line, which has the distinction of being the only inter-city cable now existent in China, is only 100 miles long. The new line probably will be completed late this year. It will cost about $500,000 and will be constructed according to American standards.

New exchanges are also being erected in most of the larger cities to augment the 55,000 subscriber lines already in use in China. Girls are being trained for operators in Shanghai for the first time. It is also probable that girls will be used in the operation of the new system in the Yangtse valley. Hitherto due to the cheapness of male labor all work at the Chinese exchanges has been done by men. It is expected that it will require ten years to give China the telephone service its more active citizens desire.

ELECTRIFICATION OF JAPANESE RAILWAYS

The official system for the electrification of the railways of Japan has recently been revised and a new electric bureau established, states an issue of the Yokohama Chamber of Commerce Journal. According to the plan now being worked out by the Department of Railways, the first steps will be to electrify the entire Tokaido line, whose traffic has been increasing enormously each year, from Tokyo to Kobe, and a part of the Central line between Iidamachi station in Tokyo and Kofu, in the rear of Mount Fuji, where many tunnels make transportation slow. Electric trains will be used exclusively for passengers, freight trains being propelled by steam as at present.

Radiation From Transmission Lines

BY JOHN R. CARSON
American Tel. & Tel. Company, New York, N. Y.

THE problem of radiation losses from transmission lines on which high-frequency currents are transmitted has become of considerable practical interest in view of the fact that in carrier wave transmission over wires, frequencies are now employed which are comparable with those utilized in radio communication. In discussing this problem I shall confine myself to a brief examination of two particular questions, the answers to which are, I believe, sufficient for engineering purposes, although they by no means constitute a complete solution of the problem.

The first question, which is suggested by some recent technical publications, may be explained as follows. In our usual engineering formulas for the propagation of alternating currents along wires, the attenuation of the current depends upon the dissipation in the wires and in the surrounding dielectric when leakage is present and vanishes in the ideal case of perfectly conducting wires in a perfectly non-conducting dielectric medium. The view appears to be rather prevalent among engineers that these formulas ignore the effect of radiation, and that in addition to attenuation by the dissipation, the current wave is also attenuated by radiation. The specific question arises, therefore, in transmission of alternating current along guiding wires, is the current wave attenuated by radiation, an effect which is entirely ignored in our usual engineering formulas.

Fortunately this question admits of a definite answer in the negative; the evidence for which I shall briefly state. Consider the case of two straight parallel wires of perfect conductivity in a perfectly non-conducting dielectric medium. The rigorous solution of the problem of wave propagation along such a system, starting with Maxwell's equations and determining the appropriate solution corresponding to the geometry of the system, is a comparatively simple problem and has been worked out long ago.[1] The result is that we find that the current is transmitted *with the velocity of light without attenuation* which agrees exactly with our engineering formulas. This is sufficient in itself to answer our first question as follows: *In transmission of alternating currents along straight guiding wires the current is not attenuated by radiation.*

This conclusion is amply confirmed by a number of investigations. For example, MacDonald in his book on Electric Waves, an Adam's Prize Essay of Cambridge University, states explicitly (Pg. 83): "It follows immediately that, for any number of parallel wires along which waves are traveling, the rate of radiation across any parallel cylindrical surface vanishes."

Again in a paper in the *Annalen der Physik,* Mie attacked the problem of wave propagation along two parallel wires in a fundamental and rigorous manner and arrived at conclusions which may be translated as follows (Pg. 248): "From an infinitely long line consisting of two parallel and equal wires of cylindrical cross-section, not the slightest trace of radiation passes out into the surrounding space even at the highest frequencies and at entirely arbitrary distances from the wires."

The foregoing conclusions are in direct disagreement with the theory recently advanced by Steinmetz (PROC. A. I. E. E., March 1919). In view of the fact that in this paper he has quite fully formulated a theory of radiation from wires which appears to be rather widely held among engineers, it may be well to summarize briefly his conclusions.

In a line which is transmitting high-frequency currents, Steinmetz states that there is, in addition to the energy consumption in the form of heat due to the ohmic resistance of the wires, an additional loss per unit length due to radiation of energy out of the system. This energy radiation, like energy dissipation by ohmic resistance, is accompanied by a counter electromotive force in the conductor or potential drop in the line. Consequently, the loss per unit length due to radiation can be accounted for by adding to the ohmic resistance per unit length of the line or conductor an additional "radiation resistance." According to this view the radiation resistance is a linear "constant" (or more precisely, parameter) of the line just as are the ohmic resistance, the inductance and the capacity. Steinmetz states that this linear radiation resistance increases as the square of the frequency when the line consists of parallel conductors (on which equal and opposite currents are flowing) provided the separation of the conductors is small compared with the wave length, which is always the case unless the frequency is enormous compared even with the highest frequency employed in radio transmission. He further states that when the line consists of a single conductor, the radiation resistance is at first directly proportional to the frequency and becomes proportional to the square of the frequency when the frequency is very high, and that the "radiation resistance" at high frequencies may be "thousands of times greater than the ohmic resistance" even when the increase of the latter with frequency is correctly taken into account.

The error which appears to underlie the conclusions of Steinmetz is strikingly similar to that commented

Presented at the April 1921 Meeting of the National Academy of Sciences.

1. See Abraham u. Föppl, Theorie der Elecktrizitat, Vol. I, pages 301-318.

on long ago by Heaviside.[2] In a discussion of transmission along wires, he points out that, in the vicinity of the wires, the energy flow is along the axes of the wires with a slight inclination *inward*. He then adds, "Professor Poynting, on the other hand (*Roy. Soc. Trans.* Feb. 12, 1885) holds a different view representing the transfer (of energy) as nearly perpendicular to a wire, *i. e.*, with a slight departure from the vertical. This difference of a quadrant can, I think, only arise from what seems to be a misconception on his part as to the nature of the electric field in the vicinity of a wire supporting electric current." Similarly all of Steinmetz' conclusions are based on the explicit assumption that the magnetic field is propagated outward from the surface of the wire at right angles to its axis with the velocity of light.

I shall now briefly take up the second question, namely the calculation of the order of magnitude of the radiation losses when high-frequency currents are transmitted over wire lines. In connection with this question the importance of the foregoing discussion is just this: Since the current is not attenuated by radiation, the energy losses due to radiation from the system as a whole must appear as terminal impedance corrections or reflection effects. To put this matter in another way, the generator in addition to the energy delivered to the line must supply the energy radiated, and our usual formulas ignore the latter effect. Again if at any point the spacing of the wires is changed or if the geographical direction of the line is changed, the amount of radiation is modified and this must appear as a reflection effect in the current wave which our formulas do not take into account. I have roughly sketched out the mathematical problems here involved. Their complexity is very great and a complete solution, so far as I am aware, has never been attempted. Fortunately, however, the representative calculation which I shall now give shows that the radiation losses to be expected from actual lines are so small as to introduce exceedingly small errors in our ordinary formulas.

The radiation from any known distribution of alternating currents can be calculated in a relatively simple and very elegant manner by making use of the Lorentz or retarded potentials by a method which appears to have been first applied to the calculation of radiation from a complicated system of currents by Poincare[3]. One ideal case of considerable theoretical and practical interest lends itself readily to calculation by this method, and the results of such calculation throw a great deal of light on the character of the phenomena and the orders of magnitude involved. This is the case of an ideal line consisting of two straight parallel wires of perfect conductivity of length x and separation y between wires. We suppose that alternating current of frequency $p/2\pi$ is transmitted along this line without attenuation and with the velocity of light c. We further suppose that the line is so terminated that there is no appreciable reflection of current. If σ denote x/τ where τ is the wave length the total radiation from the line is

$$S = 30\left(\frac{p\,y\,I}{c}\right)^2\left(1 - \frac{\sin 4\pi\sigma}{4\pi\sigma}\right) \text{ in practical}$$

units. To give a more definite idea of this magnitude let S_0 be the total radiation from a simple Hertzian oscillator of moment $y\,I$; that is a simple oscillator of length y and current I at frequency $p/2\pi$. Then

$$S_0 = 10\left(\frac{p\,y\,I}{c}\right)^2 \text{ in practical units}$$

and $$S = 3\,S_0\left(1 - \frac{\sin 4\pi\sigma}{4\pi\sigma}\right)$$

This formula is so simple as to require but little explanation. For very short lines the radiation is proportional to the fourth power of the frequency while for very long lines it is proportional to the square of the frequency and, as the length of the line is increased, approaches the limiting value

$$S \sim 30\left(\frac{p\,y\,I}{c}\right)^2 = 3\,S_0$$

As the length of the line is varied the radiation oscillates about this limiting value with decreasing amplitude. For example, when the line is 3/8 wave length long, the radiation exceeds that of the very long line by 20 per cent. If the wires are one foot apart, which is the usual spacing, and the frequency one million cycles per second, the radiation is only

$$0.0051\left(1 - \frac{\sin 4\pi\sigma}{4\pi\sigma}\right) \text{ watts / amperes}$$

That is to say the radiation effect is equivalent to an additional resistance in the generator circuit of only 0.0051 ohm. At 100,000 cycles per second, a frequency considerably higher than has as yet been commercially employed in wire transmission, this resistance is only 5×10^{-5} ohm.

To sum up, we may, I think, safely conclude that at any frequencies at all likely to be employed on actual lines the radiation effects are so small as to introduce no appreciable errors in our calculations. This conclusion is reinforced when we reflect that actual lines are transposed at frequent intervals and that the effect of such transpositions is to still further reduce the radiation losses.

Theory of Magneto-Mechanical Systems as Applied to Telephone Receivers and Similar Structures

BY R. L. WEGEL

Research Laboratories of the American Tel. & Tel. Co. and Western Elec. Co., Inc., New York, N. Y.

A sufficiently general theory of magnetic vibratory apparatus is deduced to cover all practical problems in the operation of the various types of telephone receivers as transformers of electrical into acoustical or acoustical into electrical energy. A set of linear equations is derived relating currents in windings, mounted either on a stationary support (pole piece) or on the moving part (diaphragm or armature), and the motion of the moving part. The effect of eddy currents is included by treating each eddy circulation as a circuit. From the equations derived, it is possible by simple algebraic processes to calculate the effect of eddy currents and diaphragm or armature motion in terms of the constants or impedances of the system.

By making certain constants of the equations either infinite or zero the different receiver types are represented including (1) simple receiver without eddy currents, (2) receiver with eddy currents in the pole pieces, (3) receiver with eddy currents in the diaphragm, (4) receiver with eddy currents in both pole pieces and diaphragm, (5) receiver with the driving coil on the diaphragm, and (6) receiver with non-magnetic but conducting diaphragm.

Introductory

THE theory of the permanent magnet telephone receiver was first worked out from fundamental considerations of energy, using the Lagrangian method of obtaining the equations of motion, by Poincare, *Eclairage Electrique*, vol. 50, page 221, 1907, et seq. Interesting experimental studies of the ordinary telephone receiver have been published by Kennelly and his associates. The first of these, by Kennelly & Pierce, was "The Impedances of Telephone Receivers as Affected by the Motion of their Diaphragms" (*Proceedings of the American Academy of Arts and Sciences*, 1912, Vol. 48.) The general method used throughout these studies is the inference of the characteristics of the telephone from its impedance under various conditions.

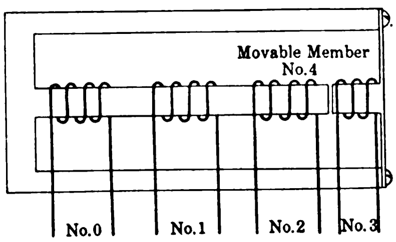

Fig. 1—Schematic Receiver

A number of other articles on the receiver has appeared in American and foreign periodicals during the last few years. They are concerned principally with methods of measurement of various constants.

This paper includes a somewhat more general theory of receiver structures and its application to the technique of measurement. The method used is applicable to any number of mutually dependent or independent electrical circuits magnetically coupled to any number of mechanical members, mutually dependent or independent. A paper by H. W. Nichols, "Theory of Variable Dynamical—Electrical Systems," *Phys. Rev.* August 1917, gives the general considerations of variable systems, of which the telephone receiver is a particular case.

General Theory

This section covers the theory of a sufficiently general electromagnetic vibratory mechanism to be applicable to any type of telephone receiver or transmitter operating on the principle of the reaction between relatively movable magnetic fields produced either by magnets or electric currents.

In Fig. 1, four coils are shown which are parts of four circuits. Coils Nos. 0, 1, 2, and 3 are situated so as to be inductively coupled each to each. Circuits Nos. 0, 1, and 2 are relatively fixed. No. 4 is a mechanical member free to move with one degree of freedom by a bending of its supports with respect to the support or core of members Nos. 0, 1, and 2. Coil No. 3 is constrained to move either with the mechanical member No. 4, or with a motion having a definite linear relation to the movement of No. 4. Fig. 1 illustrates schematically a single-pole telephone receiver. The movable member, No. 4, represents the diaphragm. Coil No. 0 carries a direct current to supply the steady magnetizing flux for the pole piece on which coils Nos. 0, 1, and 2 are mounted. Coil No. 1 represents the receiving coil which carries the telephone current. Coil No. 2 represents the eddy current circuit in the pole piece. Coil No. 3 mounted on the diaphragm represents the eddy current circuit in the diaphragm. A movement of the diaphragm, No. 4, alters the self and mutual inductances of all four electrical circuits.

Notation. Let L_0, L_1, L_2, and L_3 represent the self-inductances of circuits of which coils Nos. 0, 1, 2, and 3 are parts, L_{01}, L_{02}, L_{03}, L_{12}, L_{13}, and L_{23}, the mutual inductances between circuits as indicated by their subscripts, and L_4, the vibrating mass of the movable member.

Let R_0, R_1, R_2, and R_3 be the resistances of circuits of which the coils are parts and R_4—the mechanical dissipative resistance to motion of the movable member.

R_4 is assumed independent of the velocity of motion and gives, when multiplied by the square of the velocity of motion, the rate of dissipation of energy mechanically by the movable member. In order to conform with the electrical units adopted this resistance will be so chosen that the power dissipated is measured in watts.

Let C_0, C_1, C_2, and C_3 represent series capacitances or displacement of electricity in the condensers per unit of electromotive force in the corresponding circuits, and C_4 the mechanical "capacitance" or displacement per unit of force acting on the diaphragm. The reciprocal $1/C_4$ is the stiffness of the mechanical member.

Let i_0, i_1, i_2, and i_3 be currents flowing through the corresponding circuits, and $\dot{x}$ the velocity of motion of the movable member.

Let q_0, q_1, q_2, and q_3 be the quantities of electricity displaced as defined by $d\,q/d\,t = i$, and x the displacement of the movable member definable by $d\,x/d\,t = \dot{x}$.

Let E_0, E_1, E_2, and E_3 be the electromotive forces tending to produce displacement of electricity or current in the circuits and F the force tending to produce a displacement of the mechanical member.

f = frequency, $w = 2\,\pi\,f$ and $j = \sqrt{-1}$.

The first step in formulating a theory of this structure is to obtain the electromotive force equations or equations of motion; that is, a relation between the currents in the various circuit branches, velocity of motion of the mechanical member, electromotive and mechanical forces and electrical and "mechanical" impedances.

The reactions due to resistances and capacities in the various circuits are $i_0 R_0$, $i_1 R_1$, $i_2 R_2$, $i_3 R_3$, and q_0/C_0, q_1/C_1, q_2/C_2, q_3/C_3. Similarly the mechanical resistance and stiffness reactions are $\dot{x} R_4$ and x/C_4, respectively.

The reaction in an invariable circuit due to inductance is $L\,d\,i/d\,t$. In this case the inductances are variable, depending on the position, x, of the mechanical member. The motion is assumed to be small enough so that each inductance is a linear function of the mechanical displacement x and of the form $L\,(1 + k\,x_4)$ where L is the mean value of an inductance about which the variation takes place and k is a constant. On this assumption, $k\,x$ is small compared to unity. The inductive reactions are obtained from the kinetic energy, T, of the system by means of a differential formula due to Lagrange for mechanical systems and Maxwell for electrical systems. This formula is:

$$\frac{d}{d\,t}\left(\frac{d\,T}{d\,i}\right) - \frac{d\,T}{d\,q}$$

To get the inductive reaction in circuit No. o, i_0 and q_0 are used. The reactions in the other circuits are obtained by using the proper i and q. The mass reaction is found by using $\dot{x}$ and x.

The instantaneous kinetic energy of the whole system is

$$\begin{aligned} T = {} & 1/2\,L_0\,i_0^2 + 1/2\,L_1\,i_1^2 + 1/2\,L_2\,i_2^2 + 1/2\,L_3\,i_3^2 \\ & + 1/2\,L_4\,\dot{x}^2 + L_{01}\,i_0\,i_1 + L_{02}\,i_0\,i_2 + L_{03}\,i_0\,i_3 \\ & + L_{12}\,i_1\,i_2 + L_{13}\,i_1\,i_3 + L_{23}\,i_2\,i_3 \end{aligned} \qquad (1)$$

The force equation of any member, electrical or mechanical, is then given by an expression of the form

$$E = R\,i + \frac{q}{C} + \frac{d}{d\,t}\left(\frac{d\,T}{d\,i}\right) - \frac{d\,T}{d\,q}$$

Applying this formula to each member of the system, the following five equations of motion are obtained:

$$\left.\begin{aligned}
E_0 &= R_0\,i_0 + \frac{1}{C_0}\,q_0 + \frac{d}{d\,t}\,[L_0\,(1 + k_0\,x)\,i_0 \\
&\quad + L_{01}\,(1 + k_{01}\,x)\,i_1 + L_{02}\,(1 + k_{02}\,x)\,i_2 \\
&\quad + L_{03}\,(1 + k_{03}\,x)\,i_3] \\
E_1 &= R_1\,i_1 + \frac{1}{C_1}\,q_1 + \frac{d}{d\,t}\,[L_{01}\,(1 + k_{01}\,x)\,i_0 \\
&\quad + L_1\,(1 + k_1\,x)\,i_1 + L_{12}\,(1 + k_{12}\,x)\,i_2 \\
&\quad + L_{13}\,(1 + k_{13}\,x)\,i_3] \\
E_2 &= R_2\,i_2 + \frac{1}{C_2}\,q_2 + \frac{d}{d\,t}\,[L_{02}\,(1 + k_{02}\,x)\,i_0 \\
&\quad + L_{12}\,(1 + k_{12}\,x)\,i_1 + L_2\,(1 + k_2\,x)\,i_2 \\
&\quad + L_{23}\,(1 + k_{23}\,x)\,i_3] \\
E_3 &= R_3\,i_3 + \frac{1}{C_3}\,q_3 + \frac{d}{d\,t}\,[L_{03}\,(1 + k_{03}\,x)\,i_0 \\
&\quad + L_{13}\,(1 + k_{13}\,x)\,i_1 + L_{23}\,(1 + k_{23}\,x)\,i_2 \\
&\quad + L_3\,(1 + k_3\,x)\,i_3] \\
F &= R_4\,\dot{x} + \frac{1}{C_4}\,x + L_4\,\frac{d\,\dot{x}}{d\,t} - [1/2\,(L_0\,k_0\,i_0 \\
&\quad + L_{01}\,k_{01}\,i_1 + L_{02}\,k_{02}\,i_2 + L_{03}\,k_{03}\,i_3)\,i_0 \\
&\quad + 1/2\,(L_{01}\,k_{01}\,i_0 + L_1\,k_1\,i_1 + L_{12}\,k_{12}\,i_2 \\
&\quad + L_{13}\,k_{13}\,i_3)\,i_1 + 1/2\,(L_{02}\,k_{02}\,i_0 + L_{12}\,k_{12}\,i_1 \\
&\quad + L_2\,k_2\,i_2 + L_{23}\,k_{23}\,i_3)\,i_2 + 1/2\,(L_{03}\,k_{03}\,i_0 \\
&\quad + L_{13}\,k_{13}\,i_1 + L_{23}\,k_{23}\,i_2 + L_3\,k_3\,i_3)\,i_3]
\end{aligned}\right\} \quad (2)$$

Suppose now that the capacitance, C_0, is omitted, and a relatively large direct current flows in circuit No. 0 through a high enough impedance so that the reactions depending on $\dfrac{d\,i_0}{d\,t}$ can be considered negligible. The first equation then becomes $E_0 = i_0\,R_0$ and in this investigation will not be considered. The purpose of this circuit, it will be seen later, is only to supply a large permanent steady magnetic field. In a permanent magnet receiver this is a fictitious winding so disposed as to give the field, in magnitude and distribution, of the permanent magnet.

In the foregoing equations, i_0 occurs in products with other currents. Products of the small i_1, i_2, i_3, and x also occur. The terms containing these products involve reactions which are negligibly small

compared to those of the terms containing i_0. The term $1/2\, L_0\, k_0\, i_0^2$ is a constant entering the equation of mechanical force and determines the permanent deflection of the mechanical member from its equilibrium position. This term can be eliminated by measuring the displacement x from the equilibrium position when the large current i_0 is flowing.

If, in addition, we define

$$L_{01}\, k_{01}\, i_0 = b_{14},\; L_{02}\, k_{02}\, i_0 = b_{24},\; L_{03}\, k_{03}\, i_0 = b_{34},$$

and neglect the second order terms as explained above, the above five equations are reduced to four as follows:

$$\left.\begin{aligned} &L_1\, d\, i_1/d\, t + R_1\, i_1 + (1/C_1)\, q_1 + L_{12}\, d\, i_2/d t \\ &\qquad + L_{13}\, d\, i_3/d\, t\; b_{14}\, \dot{x} = E_1 \\ &L_2\, d\, i_2/d\, t + R_2\, i_2 + (1/C_2)\, q_2 + L_{12}\, d\, i_1/d\, t \\ &\qquad + L_{23}\, d\, i_3/dt + b_{24}\, \dot{x} = E_2 \\ &L_3\, d\, i_3/d\, t + R_3\, i_3 + (1/C_3)\, q_3 + L_{13}\, d\, i_1/d\, t \\ &\qquad + L_{23}\, d\, i_2/d\, t + b_{34}\, \dot{x} = E_3 \\ &L_4\, d\, \dot{x}/d\, t + R_4\, \dot{x} + (1/C_4)\, x - b_{14}\, i_1 - b_{24}\, i_2 \\ &\qquad - b_{34} i_3 = F \end{aligned}\right\} \quad (3)$$

It will be seen from dimensions that the quantities b_{14}, b_{24} and b_{34} are either back electromotive forces per unit velocity of No. 4 or forces on No. 4 per unit of current.

The free vibrations of this system are obtained by placing $E_1 = E_2 = E_3 = F = 0$ and solving for the free periods and the damping in the usual way. The expressions thus obtained, except for the simplest cases, are very complex and will not be of interest in connection with this treatment.

For forced vibrations, each value of E and F may be considered to be of single frequency. If a number of frequencies act simultaneously, they may be considered separately since in any system represented by a set of linear equations such as these the law of superposition holds.

We will therefore consider each value of E to be sinusoidal and to contain e^{jwt} as a factor. The forms of the i's, q's, $\dot{x}$, and x will then be complex and contain the periodic symbol e^{jwt} as a factor. Under these conditions $d/d\, t$ can be replaced by $j\, w$ and $\int d\, t$ can be replaced by $1/j\, w$. When this is done the above equations become

$$\left.\begin{aligned} &(j\, w\, L_1 + R_1 + 1/j\, w\, C_1)\; i_1 + j\, w\, L_{12}\, i_2 \\ &\qquad + j\, w\, L_{13}\, i_3 + b_{14}\, \dot{x} = E_1 \\ &(j\, w\, L_2 + R_2 + 1/j\, w\, C_2)\; i_2 + j\, w\, L_{12}\, i_1 \\ &\qquad + j\, w\, L_{23}\, i_3 + b_{24}\, \dot{x} = E_2 \\ &(j\, w\, L_3 + R_3 + 1/j\, w\, C_3)\, i_3 + j\, w\, L_{13}\, i_1 \\ &\qquad + j\, w\, L_{23}\, i_2 + b_{34}\, \dot{x} = E_3 \\ &(j\, w\, L_4 + R_4 + 1/j\, w\, C_4)\, \dot{x} - b_{14}\, i_1 - b_{24}\, i_2 \\ &\qquad - b_{34}\, i_3 = F \end{aligned}\right\} \quad (4)$$

The coefficients of currents i_1, i_2, i_3, and velocity $\dot{x}$ are seen to be impedances. Using the standard notation, Z, for impedance, these equations can be written

$$\left.\begin{aligned} Z_{11}\, i_1 + Z_{12}\, i_2 + Z_{13}\, i_3 + Z_{14}\, \dot{x} &= E_1 \\ Z_{12}\, i_1 + Z_{22}\, i_2 + Z_{23}\, i_3 + Z_{24}\, \dot{x} &= E_2 \\ Z_{13}\, i_1 + Z_{23}\, i_2 + Z_{33}\, i_3 + Z_{34}\, \dot{x} &= E_3 \\ -Z_{14}\, i_1 - Z_{24}\, i_2 - Z_{34}\, i_3 + Z_{44}\, \dot{x} &= F \end{aligned}\right\} \quad (5)$$

The significance of these equations will be better understood by pointing out their similarity to those of a familiar electrical analog.

Fig. 2 is the diagram of a four-winding transformer. Coils Nos. 1, 2, and 3 are parts of three circuits which correspond to circuits 1, 2, and 3 of the mechanism of Fig. 1. It will be of interest to compare the effect of circuit No. 4, which is like Nos. 1, 2, and 3, with that of the mechanical member, No. 4.

The same method of deriving the "equations of motion" or impedance equations can be employed for this simple transformer, but the theory of electrical networks is in such common use that this is unnecessary. The equations can be written directly.

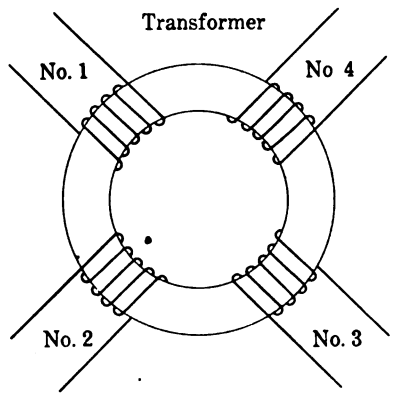

Fig. 2—Four-Winding Transformer

$$\left.\begin{aligned} &(j\, w\, L_1 + R_1 + 1/j\, w\, C_1)\; i_1 + j\, w\, L_{12}\, i_2 \\ &\qquad + j\, w\, L_{13}\, i_3 + j\, w\, L_{14}\, i_4 = E_1 \\ &(j\, w\, L_2 + R_2 + 1/j\, w\, C_2)\; i_2 + j\, w\, L_{12}\, i_1 \\ &\qquad + j\, w\, L_{23}\, i_3 + j\, w\, L_{24}\, i_4 = E_2 \\ &(j\, w\, L_3 + R_3 + 1/j\, w\, C_3)\; i_3 + j\, w\, L_{23}\, i_2 \\ &\qquad + j\, w\, L_{13}\, i_1 + j\, w\, L_{34}\, i_4 = E_3 \\ &(j\, w\, L_4 + R_4 + 1/j\, w\, C_4)\; i_4 + j\, w\, L_{14}\, i_1 \\ &\qquad + j\, w\, L_{24}\, i_2 + j\, w\, L_{34}\, i_3 = E_4 \end{aligned}\right\} \quad (6)$$

The coefficients of the currents are impedances and can be written:

$$\left.\begin{aligned} Z_{11}\, i_1 + Z_{12}\, i_2 + Z_{13}\, i_3 + Z_{14}\, i_4 &= E_1 \\ Z_{12}\, i_1 + Z_{22}\, i_2 + Z_{23}\, i_3 + Z_{24}\, i_4 &= E_2 \\ Z_{13}\, i_1 + Z_{23}\, i_2 + Z_{33}\, i_3 + Z_{34}\, i_4 &= E_3 \\ Z_{14}\, i_1 + Z_{24}\, i_2 + Z_{34}\, i_3 + Z_{44}\, i_4 &= E_4 \end{aligned}\right\} \quad (7)$$

There are two notable differences between this set of equations and that of the "magneto-mechanical" device. The mutual impedances b_{14}, b_{24}, b_{34}, between the coils and the mechanical member are constants, independent of frequency and involve no phase difference between the current and induced force, while in the transformer the corresponding mutual impedances, $j\, w\, L_{14}$, $j\, w\, L_{24}$, and $j\, w\, L_{34}$ are proportional

to frequency and involve a phase difference of 90 deg. between the inducing current and induced electromotive force. The mutual impedances, b_{14}, b_{24}, b_{34}, are of the character of resistances, in that they are in phase with the currents but are unlike resistances in that they are non-dissipative, which is shown by the fact that their signs in the electrical equations are opposite to those in the mechanical equation (See equations **4** and **5**). The analogy between the transformer and the receiver is not complete because of the difference indicated by these differences in sign.

The difference may be illustrated in another way, by an application of the "principle of reciprocity" which for a pure electrical network may be stated;

In any invariable electrical network, if any electromotive force, E, is applied in any branch and the current I measured in any other branch their ratio E/I is equal in magnitude and phase to the ratio obtained if the positions of E and the measurement of I be reversed.

This principle can be proved directly from the symmetrical form in magnitude and phase of the equations of a network of which the transformer (Eq. **7**) is an example.

The same reciprocal relation holds between displacement or velocity and mechanical force in an invariable "mechanical network," composed of any combination of elastic and inertia members, with or without damping.

In a "magneto-mechanical network" such as the one under discussion in this paper a similar principle can be formulated. For the sake of brevity a variable dynamical-electrical system in which the only variations are small changes of inductance will be alluded to as a "magneto-mechanical network."

In a "magneto-mechanical network," the ratio of an electromotive force placed in any electrical branch to the resulting displacement (or velocity) of a mechanical member (or branch) is equal in magnitude but opposite in phase (180 deg.) to the ratio of a mechanical force acting on the same mechanical member to the resulting current in the same electrical branch.

This can be proved directly from the symmetry of magnitude and asymmetry in signs in the characteristic equations No. 5, of a "magneto-mechanical network" of which the subject of this paper is an example.

In regard to the transfer of power from one circuit to another, from one mechanical vibratory element to another or from an electrical to a mechanical element or vice versa these systems are alike. For a maximum transfer of power the impedance of an element which is to be fitted to another must be the conjugate of the element to which it is fitted. This follows directly from equations 5 or 7, which are typical though not general.

A number of general expressions will next be derived for the calculation of the various currents and velocity and impedance characteristics. A set of linear equations of this kind is manipulated most easily by the short hand method of determinants.

For convenience, define

$$Z_{21} = Z_{12},\ Z_{31} = Z_{13},\ Z_{32} = Z_{23},\ Z_{41} = -Z_{14},$$
$$Z_{42} = -Z_{24},\ Z_{43} = -Z_{34}$$

Rewrite equations **5**.

$$\left.\begin{aligned} Z_{11}\,i_1 + Z_{12}\,i_2 + Z_{13}\,i_3 + Z_{14}\,\dot{x} &= E_1 \\ Z_{21}\,i_1 + Z_{22}\,i_2 + Z_{23}\,i_3 + Z_{24}\,\dot{x} &= E_2 \\ Z_{31}\,i_1 + Z_{32}\,i_2 + Z_{33}\,i_3 + Z_{34}\,\dot{x} &= E_3 \\ Z_{41}\,i_1 + Z_{42}\,i_2 + Z_{43}\,i_3 + Z_{44}\,\dot{x} &= E_4 \end{aligned}\right\} \quad (8)$$

Denote the discriminant of this system, or determinant of the coefficients of current by D, and its minors by D with proper subscripts. To illustrate: D_{13} is the first minor of D obtained by suppressing row 1, and column 3 of the coefficients; D_{13}^{24} is a second minor determinant with row 2 and column 4 eliminated in addition.

Inspection will show that a relation similar to that between mutual impedances holds for the first minors of this discriminant,

$$D_{21} = D_{12},\ D_{31} = D_{13},\ D_{32} = D_{23},$$
$$D_{41} = -D_{14},\ D_{42} = -D_{24},\ D_{43} = -D_{34},$$

In the purely electrical system, as in equations **7**, corresponding minors are identical in sign as well as in magnitude.

The solutions for currents i_1, i_2, i_3 and velocity of motion of No. 4, $\dot{x}$, are directly written.

$$\left.\begin{aligned} i_1 &= (E_1 D_{11} - E_2 D_{21} + E_3 D_{31} - F D_{41})/D \\ i_2 &= (-E_1 D_{12} + E_2 D_{22} - E_3 D_{32} + F D_{42})/D \\ i_3 &= (E_1 D_{13} - E_2 D_{23} + E_3 D_{33} - F D_{43})/D \\ \dot{x} &= (-E_1 D_{14} + E_2 D_{24} - E_3 D_{34} + F D_{44})/D \end{aligned}\right\} \quad (9)$$

As a rule, of course, only one electromotive force, E, or mechanical force, F, acts at a time so these expressions are greatly simplified by placing the others equal to zero. The expressions for various current ratios, ratios of current or velocity to applied electromotive force or mechanical force are easily written from equations 9. In particular, the ratio of any electromotive force, E, to the resulting current i in the same element is the "driving point" impedance of the system. The ratio $F/\dot{x}$ is a driving point impedance and is given in mechanical units—dynes per centimeter per second. The "driving point" impedances measured in the four circuits (the mechanical member may by analogy be referred to as a mechanical circuit) are:

$$Z_1 = D/D_{11},\ Z_2 = D/D_{22},\ Z_3 = D/D_{33},$$
$$Z_4 = D/D_{44} \quad (10)$$

Since all of the impedances are involved in these determinants, the driving point impedances Z_1, Z_2, Z_3, Z_4 are seen to depend on the reactions of all the circuits and the mechanical member.

The "damped" impedance of a receiver is the impedance of the coil measured with the diaphragm constrained from moving. This may be regarded as making the mechanical impedance infinite or "opening" the "mechanical circuit." The damped impedance of the system measured from circuit No. 1 is obtained

from the driving point impedance by suppressing row 4 and column 4. Designating the impedance measured in circuit No. 1 with No. 4 damped by Z_{1d4}:

$$\left.\begin{aligned} Z_{1d4} &= D_{44}/D_{11}{}^{44} \\ \text{Similarly } Z_{2d4} &= D_{44}/D_{22}{}^{44} \\ Z_{3d4} &= D_{44}/D_{33}{}^{44} \end{aligned}\right\} \quad (11)$$

These give the damped inpedances as measured from any of the three electrical circuits. These expressions also hold for the driving point impedance of the transformer, Fig. 2, equations **7**, with circuit No. 4 "opened."

The mechanical impedance of the vibrating member No. 4 under the influence of the reactions of circuits Nos. 2 and 3, but with No. 1 open, which by analogy can be called "damped mechanical impedance" is given similarly by

$$Z_{4d1} = D_{11}/D_{11}{}^{44}$$

Motional impedance is defined as the difference between the driving point impedance with the mechanical member free to move and with it damped.

$$Z_{1m4} = Z_1 - Z_{1d4}$$

In terms of the determinants of the system

$$Z_{1m4} = -\,D_{14}\,D_{41}/D_{11}\,D_{11}{}^{44}$$

This is typical of any electrical network as well and gives the effect on driving point impedance in any circuit No. 1, of any other circuit No. 4. In the case of the magneto-mechanical system $D_{14} = -\,D_{41}$.

$$\left.\begin{aligned} Z_{1m4} &= (D_{14})^2/D_{11}\,D_{11}{}^{44} \\ \text{Similarly} \quad Z_{2m4} &= (D_{24})^2/D_{22}\,D_{22}{}^{44} \\ Z_{3m4} &= (D_{34})^2/D_{33}\,D_{33}{}^{44} \end{aligned}\right\} \quad (12)$$

These give the motional impedances measured in any of the three electrical circuits.

In any invariable electrical, mechanical, or magneto-mechanical network, the driving point impedance Z_p measured from the p^{th} element, can be expressed as the sum of two terms, the first of which is independent of any other q^{th} circuit and the second of which is due to the reaction of the q^{th} circuit.

$$Z_p = Z_{pdq} + Z_{pmq}$$

Where

$$Z_{pdq} = D_{qq}/D_{pp}{}^{qq};\; Z_{pmq} = -\,D_{pq}\,D_{qp}/D_{pp}\,D_{pp}{}^{qq}$$

The first term may be called "damped" impedance and the second "motional" impedance.

The force per unit current in circuit No. 1 when the reactions of Nos. 2 and 3 are eliminated by "opening" is Z_{14}. A current in No. 1, however, induces currents in Nos. 2 and 3 which in turn act on No. 4 through their force factors Z_{24} and Z_{34} respectively. The total force acting on No. 4 is

$$Z_{14}\,i_1 + Z_{24}\,i_2 + Z_{34}\,i_3$$

A motion of the mechanical member causes modifying reactions on these currents producing a different force on this member than when constrained. By solving for the force resulting from unit current in circuit No. 1 after constraining No. 4 by suppressing row 4 and column 4 of the discriminant, it is found to be

$$\left.\begin{aligned} B_{1d4} &= D_{14}/D_{11}{}^{44} \\ \text{Similarly} \quad B_{2d4} &= D_{24}/D_{22}{}^{44} \\ B_{3d4} &= D_{34}/D_{33}{}^{44} \end{aligned}\right\} \quad (13)$$

These give the force per unit current in magnitude and phase with an electromotive force acting in circuits Nos. 1, 2 or 3 respectively as modified by induced currents in the other two circuits.

The electromotive force in circuit No. 1 per unit velocity of No. 4 is given by

$$\left.\begin{aligned} B_{4d1} &= D_{41}/D_{44}{}^{11} = -\,B_{1d4} \\ \text{Similarly} \quad B_{4d2} &= D_{42}\,D_{44}{}^{22} = -\,B_{2d4} \\ B_{4d3} &= D_{43}/D_{44}{}^{33} = -\,B_{3d4} \end{aligned}\right\} \quad (14)$$

This property holds generally for a "magneto-mechanical" network, and like that given above in contrast with the principle of reciprocity for invariable electrical and mechanical systems, is evident directly from the characteristic determinant by the fact that $D_{14} = -\,D_{41}$, $D_{24} = -\,D_{42}$, $D_{34} = -\,D_{43}$.

"The available force on a mechanical member per unit current in a circuit is equal in magnitude but opposite in sign to the available electromotive force in the same circuit per unit velocity of the same mechanical member."

In general, for an invariable electrical or mechanical network, or for a magneto-mechanical network,

$$B_{pdq} = D_{pq}/D_{pp}{}^{qq}$$

Motional impedance and the "damped" force factor B_{1d4} are therefore related by:

$$\left.\begin{aligned} Z_{1m4} &= \frac{(B_{1d4})^2}{Z_{4d1}} \\ \text{Similarly} \quad Z_{2m4} &= \frac{(B_{2d4})^2}{Z_{4d2}} \\ Z_{3m4} &= \frac{(B_{3d4})^2}{Z_{4d3}} \end{aligned}\right\} \quad (15)$$

Equations **15** give the most useful form for motional impedance.

The most useful substitutes for the general equations, No. 8, of motion are two in number, involving the current in the circuit in which the driving electromotive force acts and the velocity of the mechanical member on which a mechanical force may act.

$$\left.\begin{aligned} Z_{1d4}\,i_1 + B_{1d4}\,\dot{x} &= E_1 \\ B_{4d1}\,i_1 + Z_{4d1}\,\dot{x} &= F \end{aligned}\right\} \quad (16)$$

These correspond to equations No. 8 with currents i_2 and i_3 eliminated. They hold for invariable electrical and mechanical networks as well. Z_{1d4} is the apparent electrical impedance of the receiving coil and is independent of diaphragm motion. B_{1d4} is electromotive force generated in the coil per unit velocity, $\dot{x}$ of the diaphragm. B_{4d1} is force on the diaphramg per unit current in the coil and is equal to B_{1d4} in magnitude but opposite in sign. Z_{4d1} is the apparent mechanical impedance of the diaphragm. The reaction of the diaphragm in response to an applied

force is modified, both in magnitude and phase, by eddy currents.

Applications of the General Theory to Particular Receiver Structures

The application of the general theory to particular types of receivers consists in first showing the modification of the general structure, (Fig. 1) to which each corresponds, and modifying the characteristic equations (No. 5) accordingly. For example, if the simple receiver without eddy currents is to be studied the effects of circuits 2 and 3 are eliminated. In the equations the mutuals $Z_{12}, Z_{13}, Z_{23}, Z_{24}, Z_{34}$, or currents i_2, i_3, are placed equal to zero. The various types and discussions of their characteristics will be taken up separately.

A. Simple Receiver. The simple receiver is defined as one having no eddy currents in the core or diaphragm. This sort of receiver is never actually met with in practise but may be approximated by the use of high resistivity material or laminated cores and diaphragms.

The diaphragm of the receiver is not a mechanical element with one degree of freedom but may be so regarded without involving serious error. While vibrating, all parts of the diaphragm do not move with the same amplitude. The integrated product of surface density of the diaphragm and square of the velocity (r. m. s.) over the surface, gives the kinetic energy of vibration. The apparent vibrating mass, L_4 of the diaphragm is found by dividing the kinetic energy by the square of the velocity (r. m. s.) at the center. The shape of the curve of bending caused by the electromagnetic force acting about the center of the diaphragm varies with frequency of excitation, and hence, the apparent mass, L_4 must be considered as varying to a certain extent with the frequency. Similarly, the apparent elasticitance, C_4 is determined by the integrated potential energy of flexure which also varies with the frequency. The variation in L_4 and C_4 to be expected between the frequencies of zero and 3000 cycles is probably a matter of a 10 or 20 per cent gradual change for an ordinary receiver diaphragm. Similarly a variation in R_4 occurs in the receiver.

Attention must be called to the fact that even though L_4, C_4, and R_4 vary with frequency, they do not vary appreciably with amplitude of vibration at a single frequency for the small motions of a diaphragm. As a consequence, the law of superposition holds and the equations which have been deduced are valid. In complete theory, L_4, C_4, and R_4 should be replaced by their proper functions of frequency but since these changes are gradual they will not be included in this study of fundamental principles of the device.

The equations for the simple receiver are

$$\left.\begin{aligned} Z_{11}\, i_1 + Z_{14}\, \dot{x} &= E_1 \\ -\, Z_{14}\, i_1 + Z_{44}\, \dot{x} &= F \end{aligned}\right\} \quad (17)$$

From these equations we find

$$i_1 = \frac{E_1 Z_{44} - F Z_{14}}{Z_{11} Z_{44} + Z_{14}^2}$$

$$\dot{x} = \frac{E_1 Z_{14} + F Z_{11}}{Z_{11} Z_{44} + Z_{14}^2}$$

These equations give either current or velocity re-

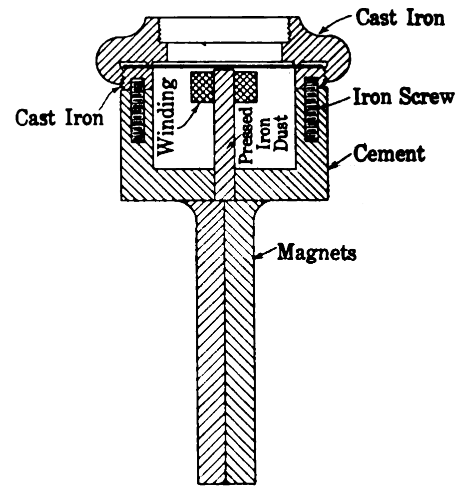

Fig. 3—Cross-Section of Experimental Receiver

sulting from an electromotive force acting in the winding as in a telephone receiver, or from a force acting on the diaphragm as in the case of a magnetic telephone transmitter, or a combination of both.

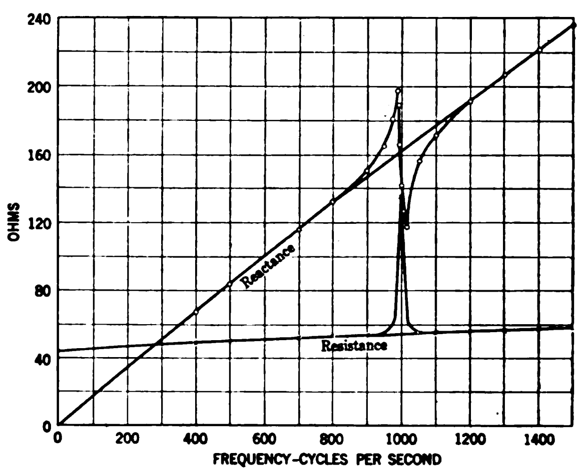

Fig. 4—Resistance and Reactance Curves of Experimental Receiver

The electrical impedance of the receiver is the ratio of the electromotive force acting to the resulting current in the coil and is given by

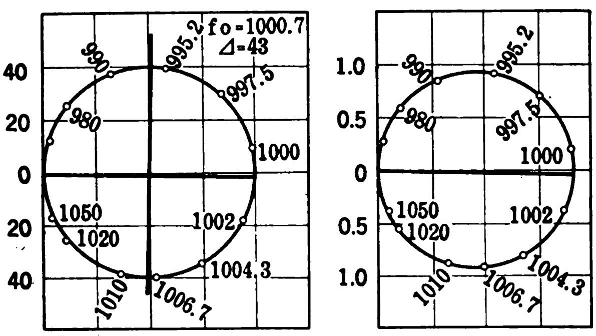
$$Z_1 = Z_{11} + Z_{14}^2 / Z_{44}$$

The damped impedance is simply the impedance of the coil Z_{11}, and the motional impedance is Z_{14}^2/Z_{44}. The "vector" locus of this motional impedance is a circle with its diameter coinciding with the real axis and tangent to the positive side of the imaginary axis.

Fig. 3 shows a cross-section of an experimental simple receiver. The pole piece was made of finely divided iron pressed together with shellac and energized by a pair of bar magnets. The cup was made of cement to reduce any possible eddy current effects and to minimize differential temperature expansions. The cap and seating surfaces for the diaphragm were cast iron. The diaphragm was a standard disk 0.009 in. thick. The coil had a resistance of 48 ohms and an inductance of 0.026 henry.

Fig. 4 shows plots of measured resistance and reactance of this receiver as functions of frequency. The eddy current effect is small as is shown by the relatively small increase in damped resistance, R, with frequency.

Fig. 5 shows the circular "vector" plots of measured motional impedance and computed velocity of motion of the center of the diaphragm at various frequencies in the region of resonance. The resonant frequency is seen to be 1000.7 cycles.



Motional Impedance Vector Plot Velocity Vector Plot

FIG. 5

The effective vibrating mass, L_4, of the diaphragm, is 0.68 gram as calculated from the observed change in natural frequency caused by adding a small known weight to the center of the diaphragm. The logarithmic decrement per second as determined from the motional impedance circle (Fig. 5) is $\Delta = 48$. The mechanical resistance, R_4, of the diaphragm obtained from the relation $\Delta = R_4/2\,L_4$ is 58.5 dynes per centimeter per second. At resonance of the diaphragm, $Z_{1m4} = b_{14}^2/R_4$. From this relation the force factor b_{14} was computed and found to be 2.18×10^6 dynes per absolute electromagnetic unit of current. The apparent elasticity $1/C_4$ of the diaphragm is 26.7×10^6 dynes per centimeter.

The mechanical impedance is the ratio of force F to velocity of motion, $\dot{x}$.

$$Z_4 = Z_{44} + Z_{14}{}^2/Z_{11}$$

Z_{44} is analogous to damped impedance because it is the impedance of the diaphragm when the electrical circuit is "damped" or "opened." Z_{14}^2/Z_{11} is analogous to motional impedance because it is the effect on the diaphragm of a "motion" of electricity in the coil. The "vector" diagram of this motional mechanical impedance is a semicircle and gives the damping effect of the circuit on the diaphragm at any frequency. If a condenser is placed in the circuit of the receiver coil the locus of Z_{14}^2/Z_{11} $(= Z_{4m1})$ is a circle exactly as in the case of Z_{1m4} but is given in mechanical units (mechanical ohms) instead of in electrical ohms.

The ratio of power dissipated in diaphragm motion to the total input is easily calculated. This ratio should not be confounded with the efficiency of the instrument as a telephone receiver because a large part of the power is dissipated in diaphragm friction as its supports and in air vibrations which do not reach the ear.

The mechanically dissipated power is *mod* $\dot{x}^2 R_4$, ("*mod*" is an abbreviation for modulus or "absolute" value). The input power is *mod* $i_1^2 R$ where R is total apparent resistance. The ratio e, at any frequency is

$$\begin{aligned} e &= mod\ (\dot{x}^2 R_4/i_1^2 R) \\ &= mod\ (Z_{14}^2 R_4/Z_{44}^2 R) \\ &= mod\ (Z_{14m4}^2/Z_{1M4} R) \end{aligned}$$

The symbol Z_{1M4} is used to denote the maximum motional impedance. At resonance, or the frequency of maximum response this reduces to

$$e_0 = mod\ Z_{1M4}/R$$

The theory of this receiver is the same as that of the vibration galvanometer.

B. Receiver with Eddy Currents in the Core. This receiver corresponds closely to the commercial instrument in which the effect of eddy currents in the diaphragm is usually small.

The theory of a receiver with eddy currents in the diaphragm only, as seen from the characteristic equations is identical with that to be considered here. A little consideration will make this apparent physically. When the diaphragm is damped an eddy current in the core obviously has the same qualitative effect as one in the diaphragm for they are coaxial. Similarly when the receiving coil, No. 1, is opened and the diaphragm moves toward the pole piece, an increase in magnetic flux in both circuits results. The damping effect on diaphragm motion is qualitatively the same due to either circuit.

We are regarding the eddy current in the core as a circuit. This is as well justified as regarding the diaphragm as a member of one degree of freedom. The principal body of eddy current flows around the core surface in a layer the thickness of which decreases roughly as the square root of the frequency. In an infinite cylindrical core inside of a solenoid the current distribution is a Bessel's function of the radial distance from the axis. Regarded as a circuit, the core eddy current consists of an elongated coil of one turn short-circuited on itself. The resistance to flow of eddy current is determined by the resistivity of the iron and the thickness of the layer. The resistance of the eddy current circuit, therefore, increases roughly as the square root of the frequency. Its inductance is fairly

constant since the flux linkage per unit current in this layer is about constant. At very low frequencies eddy currents are not confined to the surface, and the effective resistance and inductance of the eddy current circuit are, therefore, very small. The inductance approaches a constant value, as frequency increases, of the order of magnitude of the inductance of the receiving coil divided by the square of the number of turns.

In a common type of receiver having 700 turns per spool and 0.020-henry inductance, the inductance of the eddy current circuit would be of the order of $0.020/(700)^2$ or about 0.041×10^{-6} henry per pole. The eddy current circuit force factor, b_{24}, would be given, in order of magnitude, by that of the receiving winding divided by the number of turns, $5 \times 10^6/700$ or 0.71×10^4 dynes per absolute electromagnetic unit of current. As in the case of the diaphragm, the constants of the eddy current circuit vary with frequency, and to some extent with the character of the diaphragm motion, but do not vary appreciably with amplitude of current for the small values considered here.

The equations in this case are

$$\left.\begin{aligned} Z_{11}\, i_1 + Z_{12}\, i_2 + Z_{14}\, \dot{x} &= E_1 \\ Z_{12}\, i_1 + Z_{22}\, i_2 + Z_{24}\, \dot{x} &= 0 \\ -Z_{14}\, i_1 - Z_{24}\, i_2 + Z_{44}\, \dot{x} &= F \end{aligned}\right\} \quad (18)$$

By eliminating i_2 these equations can be written

$$\left.\begin{aligned} (Z_{11} - Z_{12}^2/Z_{22})\, i_1 + (Z_{14} - Z_{24}\, Z_{12}/Z_{22})\, \dot{x} &= E_1 \\ -(Z_{14} - Z_{24}\, Z_{12}/Z_{22})\, i_1 + Z_{44} + (Z_{24}^2/Z_{22})\, \dot{x} &= F \end{aligned}\right\} \quad (19)$$

In terms of quantities already defined, these equations are identical with

$$\left.\begin{aligned} Z_{1d4}\, i_1 + B_{1d4}\, \dot{x} &= E \\ -B_{1d4}\, i_1 + Z_{4d1}\, \dot{x} &= F \end{aligned}\right\} \quad (20)$$

The form of these equations is similar to that of equations (**17**) for the simple receiver. Z_{1d4} corresponds to Z_{11}, B_{1d4} to Z_{14}, and Z_{4d1} to Z_{44}. The quantity Z_{1d4} or impedance of the receiver with the diaphragm constrained has been generally defined (equations **10**). Z_{4d1} is the apparent mechanical impedance of the diaphragm when the effect of the receiving coil is eliminated by "opening."

This shows how the receiver with eddy currents in the core can be treated by the same method used for a simple receiver by defining the coil, diaphragm and mutual impedances as proper functions of frequency. The motional impedance is given by

$$Z_{1m4} = B_{1d4}^2/Z_{4d1}$$

We will now compare the characteristics of these new parameters with those of the simple receiver. In the simple receiver the force factor, Z_{14}, is a constant. In this case it (B_{1d4}) varies with frequency.

$$B_{1d4} = b_{14} - b_{24}\,\frac{j\, w\, L_{12}}{R_2 + j\, w\, L_2} \quad (21)$$

Fig. 6 shows a schematic "vector" plot of the force factor, B_{1d4}, as dependent on frequency.

The locus is a semicircle below the real axis. At low frequencies the force factor is greatest approaching b_{14}, which is in phase with the current at zero frequency. At high frequency the force factor approaches the smaller value

$$b_{14} - b_{24}\, L_{12}/L_2$$

which is also in phase with current.

The motional impedance is given by

$$Z_{1m4} = (B_{1d4})^2/(Z_{44} + Z_{24}^2 / Z_{22}) \quad (22)$$

The locus of Z_{1m4} in a "vector" plot is not a circle. For circuit and diaphragm constants such as occur in most telephone receivers it is very nearly so, however. The character of the apparent mechanical impedance of the diaphragm Z_{4d1} as influenced by eddy currents can be shown best by its expansion. (Represent the modulus or absolute value of an impedance by z.)

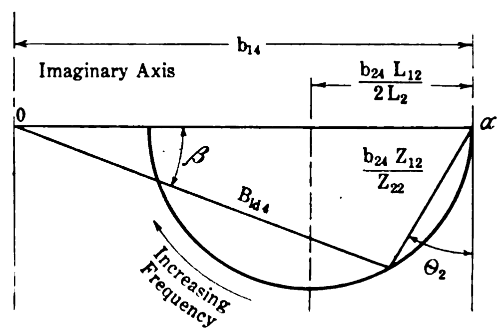


FIG. 6—SCHEMATIC "VECTOR" PLOT OF FORCE FACTOR

$$Z_{4d1} = \left(R_4 + R_2\,\frac{b_{24}^2}{z_2^2} \right) + j\, w \left(L_4 - L_2\,\frac{b_{24}^2}{z_2^2} \right) + \frac{1}{j\, w\, C_4} \quad (23)$$

The first term is the apparent mechanical resistance of the diaphragm. It is increased over the pure mechanical dissipative resistance R_4 by the addition of an eddy current component $R_2\, b_{24}^2/z_2^2$. This component decreases with frequency due to increase of z_2 with frequency.

The second term shows how the apparent mass of the diaphragm may be regarded as being decreased by the influence of eddy currents. The effect is to modify the mechanical reactance in such a way as to increase the frequency of maximum response. The decrease in apparent mass becomes less as the frequency of excitation is increased due to the variation of z_2.

The "vector" plot of the reciprocal of Z_{4d1} is not strictly a circle because of the variation of its real component with frequency. Variation of z_2 with frequency through the range of resonance of a receiver diaphragm is small enough to make the deviation from circular form inappreciable. The variation of the reactive terms has no influence on this circular form

of motional impedance. They determine only the distribution of points about the circumference of the circle and therefore lead to errors in the calculation of logarithmic decrement per second by the standard method from resonance circles or curves. The errors are only serious when the resonant region is large.

The variation in force factor B_{1d4} with frequency due to the term $b_{24} Z_{12}/Z_{22}$, representing the eddy current reaction, also produces a small deviation from circular form in motional impedance. This term shows how the eddy current produces a depression in the principal diameter of the motional impedance circle. This depression angle 2β, Fig. 6, is twice the angle of B_{1d4}. Since β is a function of frequency the angle of depression 2β, of motional impedance, is a function of the frequency to which the diaphragm is tuned, being small at low frequencies, higher at intermediate frequencies, and small at very high frequencies.

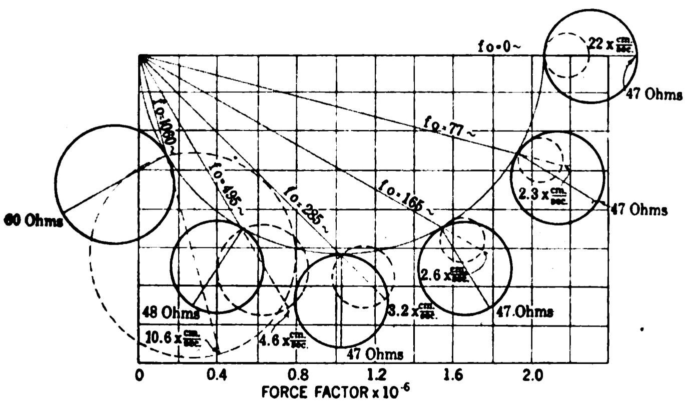

Fig. 7—Force Factor, Motional Impedance and Velocity at Different Frequencies

Velocity given per milliampere—dotted circles.

To illustrate the variation of force factor and motional impedance in this type of receiver, a simple case shown in the diagram (Fig. 7) was computed.

The constants of the experimental receiver were used with the exceptions that no mechanical resistance R_4 was assumed in the diaphragm and in place of eddy current in the core, a second winding was assumed of the same constants as the receiving coil completely coupled to it and short-circuited. In this case the force factor semicircle has a diameter of b_{14}. Motional impedance circles with the diaphragm tuned to six different frequencies are shown in heavy lines at the ends of their corresponding force factor "vectors." The frequencies of tuning are 0, 77, 165, 285, 495, and 1060 cycles. The circles increase in diameter with frequency of tuning of the diaphragm. This is because the eddy current component of damping resistance decreases at a faster rate than B_{1d4}. The dotted circles are corresponding "vector" diagrams of root mean square velocity of the diaphragm per milliampere of current in the winding. These increase in diameter indefinitely with frequency. In practise, these circles may either increase or decrease with frequency of tuning depending upon the relative magnitudes and variations of R_4, B_{1d4}, and eddy damping reaction $R_2\, b_{24}^2/z_2^2$.

The force factor semicircle can be determined experimentally for any receiver. The value of B_{1d4} is found in phase and magnitude at resonance from the motional impedance circle, or resonance curve, by a method such as that given under "Simple Receiver." By reference to Fig. 6, it will be seen that the additional measurement of the angle θ_2 determines the semicircle. The angle θ_2 is the phase angle of the eddy current circuit at the frequency of diaphragm resonance and is found from the damped impedance by the following reasoning.

$$Z_{1d4} = (R_1 + R_2\, z_{12}^2/z_2^2) + j\, w\, (L_1 - L_2\, z_{12}^2/z^2) \qquad \textbf{(24)}$$

At low frequencies the apparent resistance and inductance approach the values R_1 and L_1. These may be determined by extrapolation from measurements of damped impedance at low frequencies. The differences between the damped resistance and inductance at resonance and these values give the last terms in these two parentheses. The ratio of the differences give, $\tan \theta_2 = w\, L_2/R_2$. Having found the semicircle, the force factor B_{1d4} can be found at any frequency by simply measuring θ_2 in this way from the damped impedance, drawing a line from "a" (Fig. 6) at this angle. The line connecting its intersection with the semicircle and the origin is the force factor at the frequency in question.

A variation in inductance L_2 of the eddy circuit will cause a deviation from the circular form of the force factor locus through the speech range of the frequencies and above it. The eddy circuit inductance is usually very nearly constant in commercial receivers. The variation in the resistance R_2 of the eddy circuit alters the simple theoretical distribution of points about this locus. R_2 increases indefinitely with frequency. This tends to retard the progress of the force factor around this locus as frequency increases. In one type of receiver investigated with a single cylindrical core, the eddy current resistance approaches linear increase with frequency such that the eddy current phase angle θ_2 approaches a constant value of about 70 deg. instead of 90 deg. at high frequencies.

To illustrate the application of this theory, an analysis of a particularly efficient standard bipolar head receiver was made. It is assumed that the coils and eddy currents in the two poles are approximately the same. This allows of treating two eddy circuits as one. Fig. 8 shows curves of measured resistance and reactance plotted as functions of frequency from 0 to 1500 cycles. The distortion of these curves from a smooth variation in the neighborhood of 1000 cycles is due to a large vibration of the diaphragm in the region of its natural frequency. In a small region between 1000 and 1050 cycles, the vibration of the diaphragm is in such a phase and large enough actually to give the receiver as a whole an effective capacity reactance.

The smooth curves are drawn asymptotically and represent to a fair accuracy the "damped" values which would be obtained by restraining diaphragm motion. The circular "vector" plot of motional impedance is given in Fig. 9. The frequency of the maximum response of the diaphragm is 1005 cycles, at which the

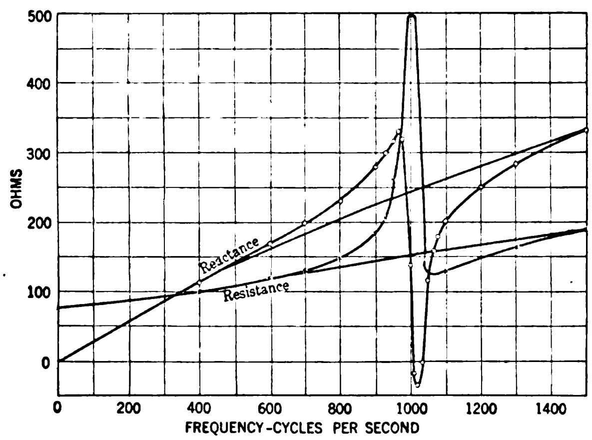

Fig. 8—Standard Bipolar Head Receiver—Resistance and Reactances Curves

motional impedance is $332 - j\,180$ or 380 ohms at an angle 2β of $-$ 28.5 deg. The logarithmic decrement per second, of the diaphragm is 138. This is obtained from the circle by multiplying the difference between the frequencies at opposite ends of the diameter perpendicular to the principal diameter of the motional impedance circle by π.

The apparent mass of the diaphragm $(L_4 - L_2\, b_{24}^2/z_2^2)$ is 0.400 gram. This is found by a calculation from the measured change in frequency of maximum response by the addition of a small known mass at the center of the diaphragm. The resistance to motion of the

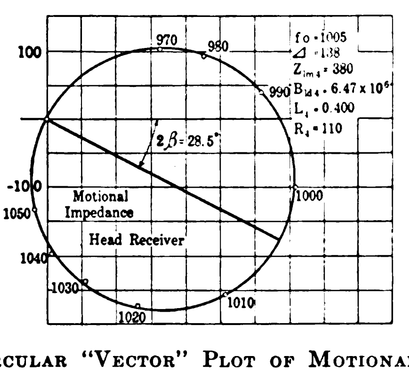

Fig. 9—Circular "Vector" Plot of Motional Impedance

diaphragm $(R_4 + R_2\, b_{24}^2/z_2^2)$ is 110 dynes per centimeter per second and is found from the relation

$$\Delta = (R_4 + R_2\, b_{24}^2/z_2^2)/2(L_4 - L_2\, b_{24}^2/z_2^2)$$

The motional impedance is given by

$$Z_{1m4} = B_{1d4}^2/(Z_{44} + Z_{24}^2/Z_{22})$$

(see equation 22), which owing to the cancelling of the mass and elastic reactances of Z_{44} becomes at the frequency of maximum response

$$Z_{1m4} = B_{1d4}^2/(R_4 - R_2\, b_{24}^2/z_2^2)$$

From this, the damped force factor B_{1d4} was computed at the frequency of maximum response to be $(6.28 - j\,1.59) \times 10^6$ or 6.47×10^6 dynes per absolute electromagnetic unit of current, at an angle of $-$ 14.3 deg. This is plotted "vectorially" in Fig. 10, the reference phase being that of i_1, the current in the receiving winding. The semicircle given in this figure is the locus of B_{1d4} as frequency is varied. The force factor at zero frequency, b_{14}, is 8.44×10^6 and is in phase with the received current. The semicircular locus was determined by the method given in the discussion of equation **21**. The force factors at 500 and 1500 cycles are also given.

The part of the resistance due to eddy current $(R_2\, b_{24}^2/z_2^2)$ is computed to be 42 dynes per centimeter per second which is about 38 per cent of the total. The eddy current component of resistance is computed from the force factor diagram, Fig. 10, and damped

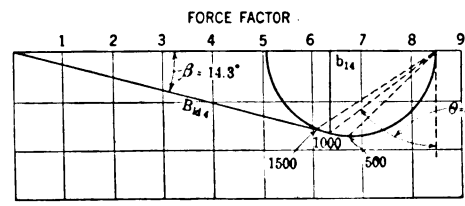

Fig. 10—Head Receiver-Plot of Force Factor B_{1d4}

impedance, Fig. 8. A little calculation will show that this is equal to the product of the real and imaginary components of the "vector," $-\, b_{24}\, Z_{12}/Z_{22}$ of the experimentally determined force factor diagram (of Fig. 6) divided by $w\, L_2\, z_{12}^2/z_2^2$ obtained from damped reactance (see discussion of equation **24**).

The apparent mass of the diaphragm is 0.400 gram. This is less than the purely mechanical apparent mass by 0.009 gram or about 2 per cent which gives an increase in maximum response frequency of about 10 cycles. The eddy current component of apparent mass can be seen to be equal to the product of the real and imaginary parts of the "vector" $-\, b_{24}\, Z_{12}/Z_{22}$ in the force factor diagram divided by the product of the radial frequency w, and the added damped resistance $R_2\, z_{12}^2/z_2^2$ due to eddy currents (see equation **24**).

C. Simple Induction-Type Receiver. In principle, an ordinary telephone receiver using a non-magnetic conducting diaphragm such as aluminum or copper is an inefficient induction receiver. The most familiar example of a device working on this principle is the Fessenden submarine oscillator. Motion of the diaphragm causes no change of inductance of any circuit except the eddy current circuit on the diaphragm which moves with it. This circuit is No. 3 in Fig. 1. As a consequence, $b_{14} = b_{24} = 0$. b_{34} is therefore the only acting force factor.

Excluding all eddy currents other than that in the diaphragm, the characteristic equations are

$$\left.\begin{aligned} Z_{11}\, i_1 + Z_{13}\, i_3 \qquad\quad &= E_1 \\ Z_{13}\, i_1 + Z_{33}\, i_3 + Z_{34}\, \dot{x} &= O \\ - Z_{34}\, i_3 + Z_{44}\, \dot{x} &= F \end{aligned}\right\} \quad (25)$$

Eliminating i_3

$$\left.\begin{aligned} (Z_{11} - Z_{13}^2/Z_{33})\, i_1 + (- Z_{34}\, Z_{13}/Z_{33})\, \dot{x} &= E_1, \\ - (- Z_{34}\, Z_{13}/Z_{33})\, i_1 + (Z_{44} + Z_{34}^2/Z_{33})\, \dot{x} &= F \end{aligned}\right\} \quad (26)$$

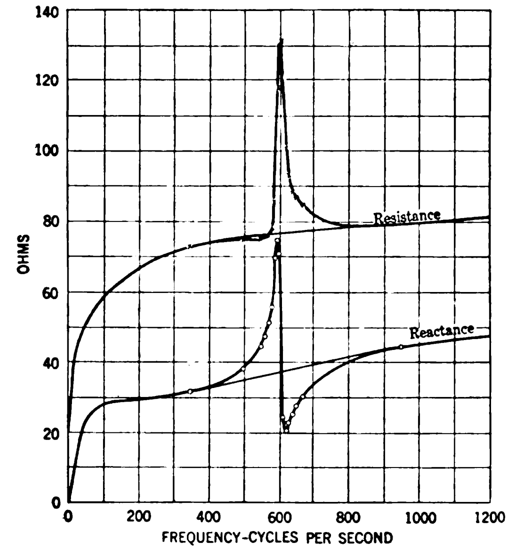

FIG. 11—INDUCTION-TYPE RECEIVER—RESISTANCE AND REACTANCE CURVES

Following the reasoning given under "*B. Receiver with Eddy Currents in the Core.*" These equations are identical with

$$\begin{aligned} Z_{1d4}\, i_1 + B_{1d4}\, \dot{x} &= E_1 \\ - B_{1d4}\, i_1 + Z_{4d1}\, \dot{x} &= F \end{aligned} \quad (27)$$

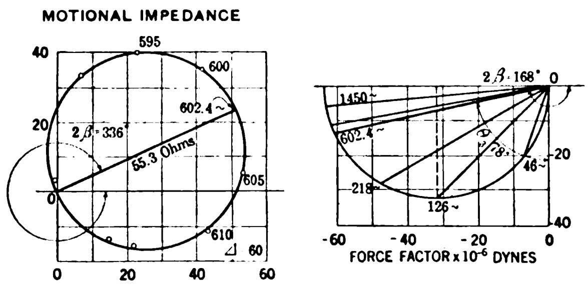

FIG. 12—INDUCTION-TYPE RECEIVER—MOTIONAL IMPEDANCE AND FORCE FACTOR DIAGRAMS

These are the equations of the induction-type receiver reduced to the form of the simple receiver. As before the motional impedance is given by

$$Z_{1m4} = B_{1d4}^2/Z_{4d1}$$

The forms of Z_{1d4} and Z_{4d1} are identical with the former case and the same discussion holds here. The force factor B_{1d4} and the motional impedance Z_{1m4} are somewhat different.

Fig. 11 shows the curves of measured resistance and reactance as a function of frequency for an experimental induction-type receiver. The smooth asymptotic curves represent damped values.

Fig. 12 shows the motional impedance and force factor diagrams of this receiver at different frequencies.

The force factor for an induction-type receiver is given by

$$B_{1d4} = - b_{34}\, \frac{j\, w\, L_{13}}{R_3 + j\, w\, L_3} \quad (28)$$

By comparison with equation **21**, it will be seen that this has the same semicircular form as the force factor

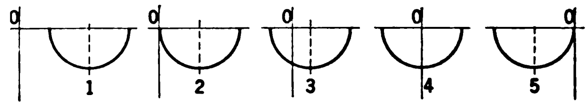

FIG. 13—POSSIBLE FORCE FACTOR SEMICIRCLES

for a receiver with eddy currents in the core, but is displaced on the real axis to a point of tangency on the negative side of the imaginary axis. This is due to the absence of the direct force factor, b_{14}, between the receiving winding and the diaphragm. In order for this type of receiver to be efficient, the semicircle must be large, and the phase angle, θ_3, of circuit No. 3 must be large. This means that R_3 must be small.

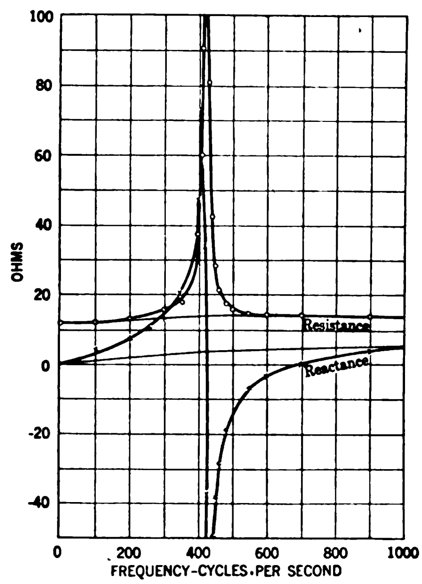

FIG. 14—ELECTRODYNAMIC RECEIVER—RESISTANCE AND REACTANCE CURVES

The force factor is determined experimentally by the same method as that used in the previous case "B".

The angle, 2β, of maximum motional impedance is 336 deg. and that of the force factor at this frequency is $\beta = 168$ deg. at the frequency, 602.4 cycles, of resonance. The phase angle of circuit No. 3 is $\theta_3 = 78$ deg. at resonance. The theory of this apparatus when used to receive mechanical energy is obtained from the equations by allowing the vibrating force F to act instead of the electromotive force E_1.

It is interesting to note that the theory of this system is the same as that for the simple receiver

(without eddy currents) but working through a transformer.

The force factor semicircles of cases "B" and "C" are in a sense closely related.

$$B_{1d4} = Z_{14} - Z_{24}\, Z_{12}/Z_{22}$$

This is the equation of the force factor for case "B". By changing the relative values of the first and second terms, the semicircle representing it is moved along the real axis from any position on the positive side (Z_{14} larger), down through a point of tangency on the positive side of the imaginary axis as in Fig. 6 to tangency on the negative side which corresponds to the induction-type receiver in which case $Z_{14} = 0$. Fig. 13 illustrates a series of possible force factor circles with one circuit in addition to the receiver circuit, No. 1.

Diagram 1. $b_{14} > b_{24}\, L_{12}/L_2$

This is the case in which the eddy current is least. If the semicircle shrinks to a point we have a case of a simple receiver.

Diagram 2. $b_{14} = b_{24}\, L_{12}/L_2$

For this condition it is necessary that circuits Nos. 1 and 2 have 100 per cent inductive coupling. Fig. 7 illustrates this case.

Diagram 3. $b_{24}\, L_{12}/L_2 > b_{14} > b_{24}\, L_{12}/2\, L_2$

This is the first case in which the phase of the force factor can be greater than 90 degrees.

Diagram 4. $b_{24}\, L_{12}/2\, L_2 = b_{14}$

The magnitude of the force factor here is independent of frequency but its phase increases from zero to $-$ 180 deg.

Diagram 5. $b_{14} = 0$

This is the case of the induction-type receiver, or simple receiver, working through a transformer.

D. Electrodynamic Receiver. The electrodynamic receiver operates by placing the driving coil on a movable member or diaphragm which is non-magnetic. Referring to Fig. 1, this case corresponds in principle to using coil No. 3 as the receiving coil. The theory of this case is identical with that for the vibration galvanometer which corresponds to a simple receiver if no eddy currents are present.

We will consider the case where an eddy circuit No. 2 is present in the stationary magnetic poles supplying the polarizing flux. The characteristic equations are

$$\left.\begin{aligned} Z_{22}\, i_2 + Z_{23}\, i_2 \qquad\qquad &= 0 \\ Z_{23}\, i_2 + Z_{33}\, i_3 + Z_{34}\, \dot{x} &= E_3 \\ - Z_{34}\, i_3 + Z_{44}\, \dot{x} &= F \end{aligned}\right\} \quad (29)$$

This is different from the induction-type receiver, case "C," only in that the driving electromotive force acts in circuit No. 3 instead of the stationary circuit. In this case we are interested in the impedance measured from circuit No. 3.

Eliminating i_2

$$\left.\begin{aligned} (Z_{33} - Z_{23}^2/Z_{22})\, i_3 + Z_{34}\, \dot{x} &= E_3 \\ - Z_{34}\, i_3 + Z_{44}\, \dot{x} &= F \end{aligned}\right\} \quad (30)$$

As before the coefficient of i_3 in the first equation is the damped impedance Z_{3d4} of the receiver. The force factor is independent of frequency and uninfluenced by the eddy current. The motion of the diaphragm is independent of eddy current which adds no electromagnetic damping.

$$Z_{3m4} = Z_{34}^2/Z_{44}$$

Motional impedance as in the case of the simple receiver is represented by a circle with its principal diameter coinciding with the real axis as in the case of the simple receiver. Eddy currents act simply as an inductively coupled external circuit.

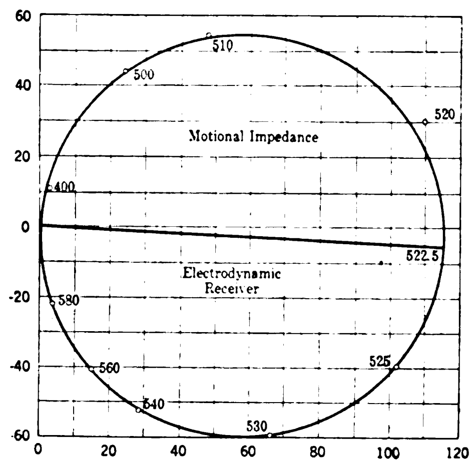

Fig. 15—Vector Plot of Motional Impedance

Fig. 14 shows plots of measured resistance and reactance of such a receiver. Fig. 15 is a vector plot of motional impedance. The natural frequency is 522.5 cycles. The depression angle of maximum motional impedance is small due to a small effect of eddy current in the coil supports on the diaphragm.

Conclusion

The object of this paper is to reduce the theory of typical magneto-mechanical vibratory structures to the simplicity of the electrical network theory, which amounts essentially to a manipulation of complex algebra.

The method is illustrated by experimental data on representatives of the leading types of magnetic receivers and transmitters. It is equally applicable to types having any number of circuits or mechanical vibratory systems including electromagnetic galvanometers and meters.

Rates for Electrical Energy and Service

BY F. W. C. BAILEY
Consulting Engineer of Columbus, Ohio

WITH the fact that nearly 500 bituminous coal mines in this vicinity are served wholly or in part by central station power service, this discussion of power rates has been prepared principally for the A. I. M. E. members, assuming that the members of the A. I. E. E. section of this joint meeting are more or less familiar with the various forms of rate schedules.

It is about as impossible to frame a power rate exactly correct for each consumer as it is for a life insurance company to name an exact rate (based on cost) for each risk that it assumes. Rates are necessarily based upon classifications, diversity factors and averages as well as costs of production. When the entire output is taken by one consumer an exact rate is a simple matter, but when thousands of consumers, distributed over a hundred or more square miles of territory, are served under all sorts of conditions, the preparation of equitable rate schedules is quite another matter.

An ideal schedule, especially for small consumers, would be one so simple that the purchase of service could be as easily made as visiting the grocery for staple articles. Most power schedules, even those available to small users, are so bewildering to the layman as to frequently breed distrust in their fairness and the "conscientious objectors" are generally more numerous among the smaller users.

The "straight line" meter rate, which is the simplest form of meter rate, has a constant unit price per kilowatt-hour, which does not vary on account of an increase or decrease in the number of units used, hence the average price is shown by a straight horizontal line. This form of rate schedule is generally confined to residence and small commercial business which carries a minimum monthly charge of 50 cents to $1.50.

The "step" meter rate is one in which the entire consumption is billed at a single price, which depends upon the particular "step" within which the total consumption falls. It is generally expressed as follows:

10	cents per kw-hr. for	1 to 20 kw-hr.
8	" " " "	21 " 40 "
6	" " " "	41 " 100 "
5	" " " "	101 " 200 "
3	" " " "	more than 200 kw-hr.

The curve of operation of this form of schedule is shown in Fig. 1 and it is apparent at a glance that very slight variations in consumption will often create very material differences in unit prices and total bills, for instance, 180 kw-hr. at 5 cents = $9.00 and 210 kw-hr. at 3 cents = $6.30, an increase in consumption of one-sixth, reducing that total bill by 30 per cent. This form of rate has the further disadvantage of not being based upon load factor, which is a vital factor in costs.

The "block" meter rate provides a price or charge for any part or all of certain specified blocks of consumption, with reduced prices per kw-hr. for each succeeding block or any portion thereof. This rate is as easily understood by consumers as the step rate and it avoids the wide variations in prices and total bills, with relatively small differences in consumption, which is characteristic of the step rate. The influence of load factor on costs is ignored, but this defect is often corrected by providing a demand or ready-to-serve charge,

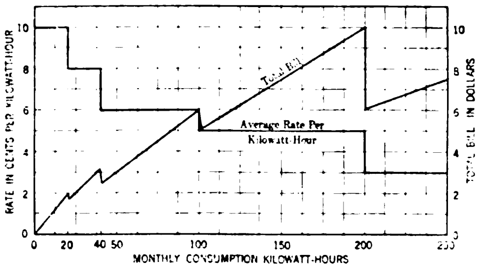

FIG. 1—STEP METER RATE

in addition to the energy charge, this combination method being known as the Hopkinson demand rate. The ordinary block rate is generally expressed as follows:

10	cents per kw-hr. for the first	20 kw-hr.
8	" " " " " next	20 "
6	" " " " " "	60 "
5	" " " " " "	100 "
3	" " " "	all excess over 200 kw-hr.

The bills under the block rate are figured as follows:

20 kw-hr.	at 10 cents	=	$2.00
20 "	at 8 "	=	1.60
35 "	at 6 "	=	2.10
			$5.70

The average price paid under this bill is 7.6 cents per kw-hr.

The following block rate schedule is in use by an Ohio central station and this form of general power schedule is commonly used by smaller utilities.

5	cents per kw-hr. for	1 to 200 kw-hr.
4.5	" " " "	201 to 350 "
4	" " " "	351 to 550 "
3.5	" " " "	551 to 800 "
3	" " " "	801 to 1800 "
2.5	" " " "	1801 to 2500 "
2.25	" " " "	2501 to 3500 "
2	" " " "	3501 or over "

Presented at the combined meeting of the Pittsburgh Sections of the A. I. E. E. and A. I. M. E., Pittsburgh, Pa., January 21, 1921.

One consumer with a 5-h. p. motor (4.5 kw. demand) operating 200 hours per month at 80 per cent average load will use about 720 kw-hr. with a load factor of about 22.2 per cent, while another consumer with a 15-h. p. motor (13-kw. demand) often uses a similar amount of energy, with a load factor of about 7.7 per cent, both consumers paying identical unit and total costs for the service. The 15-h. p. consumer should

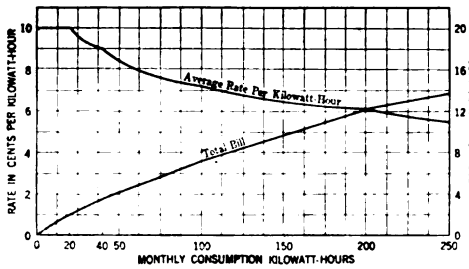

Fig. 2—Block Meter Rate

pay (based on a load factor cost basis) between 2 and 2.5 times the rate per kw-hr. that the 5-h. p. user should pay. This schedule probably yields a proper average return from the total power business, but it does not provide the proper relative returns from the high and low factor consumers.

The term "demand rate" is given to a method of charge which is based upon the capacity of a consumer's installation or his maximum demand, expressed in kilowatts or horse power (which may be either estimated or measured) during a given period of time, usually a month or a year.

The term "flat demand rate" is given to a charge for service based upon the user's installation of energy-consuming devices and is frequently modified by the "step" or "block" method. It is frequently used for residence service and is expressed as follows:

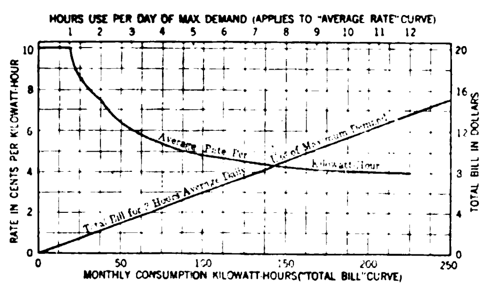

Fig. 3—Wright Demand Rate

$2.00 per month per 100 watts connected load, or
25.00 per year per horse power of connected load, or
50.00 per year per kw. for the first 25 kw. of demand.
30.00 per year per kw. for the excess above 25 kw.

The "Wright demand rate" is a method in which a maximum unit price is charged for a given amount of energy, with several reduced charges (on the block principle) for additional energy supplied, the rates being based upon the use of the maximum demand (load factor basis) which may be either estimated or measured. This rate schedule is generally applied to the larger commercial lighting and power users and is expressed as follows:

10 cents per kw-hr. for the first 30 hr. use of the demand.
6 cents per kw-hr. for the next 30 hr. use of the demand.
4 cents per kw-hr. for all energy in excess of 60 hr. use of demand.

The bill for a consumer having 10 kw. of demand and a consumption of 750 kw-hr. (equivalent to 75 hours' use of the demand) is prepared as follows:

300 kw-hr. (30 hours × 10 kw.)	at 10 cents	=	$30.
300 " "	at 6 "	=	18.
150 " "	at 4 "	=	6.
			$54.00

The average price per kw-hr. of energy used is 7.2 cents. The operation of this schedule is shown in Fig. 3.

The "Hopkinson demand rate" method consists of a demand charge to which is added an energy charge

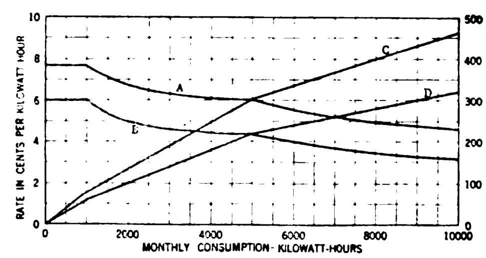

Fig. 4—Block Hopkinson Demand Rate

based upon metered energy used. The demand charge is generally based on the connected load for small installations and upon a measured demand for large installations. This rate schedule is expressed as follows:

Demand Charge:
$2.40 per kw. per month for 50 or less kw. of demand.
2.00 per kw. per month for the excess over 50 kw. of demand.
Energy Charge:
5 cents per kw-hr. for the first 100 kw-hr. used.
3 cents per kw-hr. for the next 4000 kw-hr. used.
1 cent per kw-hr. for the excess over 500 kw-hr. per month.

The bill for a consumer having 100 kw. of demand and an energy consumption during the month of 7000 kw-hr. is prepared as follows:

Demand Charge:		
50 kw. at $2.40 =	$120.	
50 kw. at $2.00 =	100.	
		$220.00
Energy Charge:		
1000 kw-hr. at 5 cents =	$50.	
4000 kw-hr. at 3 " =	120.	
2000 kw-hr. at 1 " =	20.	
		$190.00
7000 kw-hr.	Total Bill	$410.00

The average price per kw-hr. of energy used is about 5.86 cents.

The operation of this schedule is shown in Fig. 4.

Curve *A* is the average rate per kw-hr. for 3 hours average daily use of the maximum demand and curve *B* is the same data for 8 hours use. Curves *C* and *D* show respectively the total bills for 3 hours and for 8 hours use of the demand.

The "Doherty rate," or "three charge rate" (proposed in 1900 by Mr. Henry L. Doherty) is a method consisting of a customer's charge ($1.00) per month per meter) plus a demand charge, plus an energy

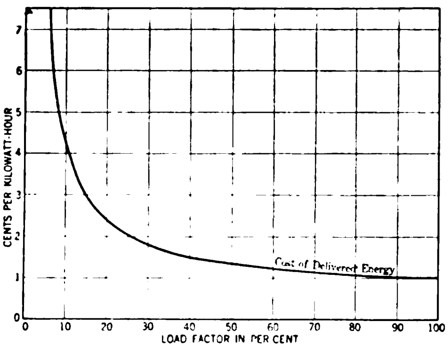

FIG. 5—COST OF DELIVERED ENERGY

charge for metered energy supplied. This form of schedule is not used in this vicinity, hence an explanation of it will not be made.

There is a tendency to question the merits of the "service-at-cost" method of rate fixing, which has been but little used in rates other than railway fares. The recent public statement of Mr. E. I. Lewis, Chairman of the Indiana Public Service Commission, is indicative of this tendency. The writer is of the opinion that it will not nor should not find any but very limited application in light and power rates.

Application has been recently made to the West Virginia Public Service Commission for the use of Zone rates for the purpose of "equalizing" the rates for electricity by providing an additional charge, for all consumers outside a given area, to compensate for additional expenses of transmission. This is an unusual method and is not likely to find very general approval, application or use even for very large and widely extended systems.

In most states the income of the utility from municipal street lighting service is given little or no consideration in connection with questions of commercial and domestic rates, this income being treated as a "voluntary" rate of the company (which the commission cannot change) and whether the contract is a source of profit or loss is not pertinent to the question of the resonableness of other rates.

A general or large power rate schedule should be based upon and conform to a load factor cost curve. From records of annual kw-hr. output through plant switchboard, kw-hr. accounted for by consumers' meters, station load factor, investment or property valuation and operating expenses, an average delivered cost curve, for all load factors, can be readily constructed. The rate of return on the investment or valuation and minor items, such as taxes and insurance, enter into the calculations, depreciation being made part of operating expenses.

The curve, Fig. 5, shows the relation of the cost of delivered energy to load factor, assuming, for convenience, that the cost of service at 100 per cent load factor is one cent. The "curve" from 75 per cent to 100 per cent load factor is almost exactly a straight line, the cost at 75 per cent being 1.119 of that at 100 per cent load factor. The cost of service at 50 per cent load factor is 1.357 that at 100 per cent and 1.213 that at 75 per cent load factor. Below 50 per cent the curve rises more sharply and the cost at 25 per cent load factor, which is fairly representative of a bituminous coal mine in this vicinity, is 1.525 that at 50 per cent load factor. The relation of costs at various other load factors is readily ascertained by reference to the curve.

Load factor expressed in hours use of demand is as follows:

Hours use per day	Equivalent Load Factor	Hours use per day	Equivalent. Load Factor
1	4.2%	13	54.3
2	8.3	14	58.3
3	12.5	15	62.5
4	16.6	16	66.6
5	20.8	17	72.
6	25.	18	75.
7	28.2	19	78.
8	33.3	20	84.
9	37.5	21	88.
10	41.7	22	92.
11	45.8	23	96.
12	50.	24	100.

The shape of this curve is derived from an annual revenue of 25 per cent of the investment or valuation, operating expenses at 60 per cent of the revenue, a return of 8 per cent on investment, reserves and surplus of 2 per cent of investment, one hour station peak loads of 80 per cent of plant capacity, a load factor of 50 per cent based on one hour peaks and 85 per cent of the output through station switchboard accounted for by consumers' meters.

The effect of "load factor" on the cost of production of coal (your own product) should be familiar to those in contact with mine operation cost accounts. Some of you have probably made estimates or "dreamed dreams" of what your production costs should or could be with a 100 per cent car and labor supply, a few pages of unfilled orders always ahead of you and 300 to 310 working days per year, in other words an 80 per cent to 85 per cent load factor, based on 365 days.

A mine has this advantage on "demand"; a large demand for coal for shipment tomorrow will be met

by shipping your output and the unfilled remainder may go forward the next day, or the next, or you may buy a few cars and fill out the order, the consumer meanwhile has a few days stock on hand. When you throw in the switches on your motors on hoists, fans, pumps, locomotives, tipples, mining machines, etc., all the power that you need must be delivered at that instant and for as long as you need it. You will pardon this garrulous remark, but the power company cannot ship you a "load of assorted amperes and volts" today and promise you another car tomorrow, and you have none in stock "to hang on your trolley wire."

In several power rate schedules, which the writer has analyzed, the demand or readiness-to-serve charge set up was found to be low in proportion to the total price paid for the service, resulting in a rate more favorable to the low load-factor consumer. In several sliding scale demand rates, which I have had occasion

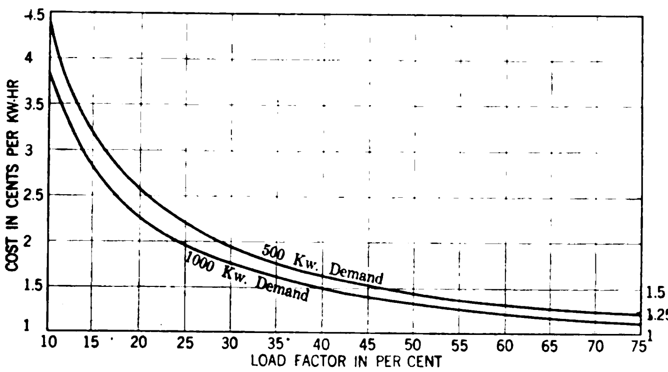

FIG. 6—SCHEDULE "J" RATES

to examine, the variation of price per kw., between small and large demands, did not run even approximately true to the actual variations in cost of readiness-to-serve. Large power schedules generally provide for a measured demand, for an interval of 5 or 15 minutes or one hour.

Most large power rate schedules specify a demand charge and an energy charge (in addition to the demand charge), but the same total prices for service at various load factors can be made, without the use of a separate demand charge, by means of a relatively high rate for the "primary" block of energy used and a low rate for the secondary or tertiary blocks of energy. An example of this method is afforded by Schedule "J" of the West Penn Power Co., with which many of you are already familiar. This schedule provides a charge of 6 cents gross per kw-hr. for the first 70 hours use of the demand and 1¼ cents gross per kw-hr. for all energy in excess of the first 70 hours use, with block discounts of from 2½ per cent to 43 per cent. The operation of Schedule "J" for a demand of 500 kw. and for 1000 kw. is shown in the curve, Fig. 6.

Where the franchise limitations of the maximum permissible rate for power service give a rate which is below the cost of low load-factor service, a minimum bill is sometimes set up which will assist in avoiding a loss or a discrimination in favor of the low load-factor consumer. It often occurs that a utility is compelled, by its inability to name equitable rates for low load-factor users, to discriminate in its rate schedules against the high load-factor user, which is its most desirable business.

Most large power schedules penalize low power factor of the consumer's service. Some provide that the average power factor shall be the basis although the detriment occasioned by low power factor is almost invariably greatest during peak hours, the effect of low power factor at other hours being localized. The recording of the time and periods of low power factor and the complications and expense of figuring bills have led to the adoption of the average power factor as the commercial basis in rate schedules. Lightly loaded induction motors are generally the source of low power factor, and it often pays, on installations of any considerable size, to provide for power factor correction where penalties are attached to rate schedules.

Power rate schedules of one large utility provide that, for demands of more than 100 kv-a., a correction factor (on the kw-hr. used) shall be applied for average power factors above and below 85 per cent for the month.

Effective P. F.	Constant	Effective P. F.	Constant.
100	0.951	80	1.023
95	0.965	75	1.05
90	0.981	70	1.0835
85	1.000	65	1.125

This method has several advantages and provides a penalty for less than 85 per cent power factor and a bonus for power factors above 85 per cent which, in my opinion, is the proper power factor in most cases for general application of unity meter registration in large power schedules.

In large power schedules, provision is sometimes made for a special and lower rate in consideration of the privilege of temporarily interrupting the service to the consumer in event of shortage of power. Many of you will probably realize the impracticability in most cases of controlling the service to certain users supplied from a large network of power circuits. A provision of this character often amounts to a special concession and a discriminatory rate, with the privilege of disconnection as an apparently plausible excuse.

The terms and conditions of contract are often but little less in importance than the rates themselves. The inclusion of instantaneous peak ratings, kv-a. rating penalties for even relatively high power factors, often results in considerable increases in the cost of service at given unit rates for demand and energy. The subject of terms and conditions of contract is too broad and complicated to discuss at this time.

There are numerous variations and combinations of the typical rates outlined above, also many methods of determining the amount of the maximum demand and of making a charge for it. A Wright demand schedule sometimes contains eight or ten steps of ratings, between 10 and 500 h. p. Straight line meter rates may be modified by several steps of discounts or reduced charges which vary with guaranteed minimum bills. Any of the various typical rates may carry 3 or 6 or 10 or any number of discounts. A block rate schedule may carry a list of 8 or 10 load-factor discounts. There are many minds at work on rate schedules and many conditions to be met, hence the numerous forms of schedules and of terms and conditions of contract.

The voltage regulation of the supply circuit often has a bearing on the cost and quality of the power service; for instance, kv-a. peaks (sometimes the basis of demand charges) are accentuated by low voltage, on certain types of equipment. The use of synchronous converters is sometimes not permissible because of inferior voltage regulation of the supply. The a-c. input being electrically connected (through the converter windings) to the d-c. feeders, the a-c. voltage fluctuations are reflected in the d-c. voltage. Excessive fluctuations in a-c. voltage generally result in serious operating difficulties with synchronous converters. Motor-generators afford much more reliable operation under these conditions, although the electrical efficiency is much lower than that of synchronous converters.

Synchronous converters, instead of motor-generators, were recently selected for two mine substations, where conditions for their use were favorable and no power factor correction was required, as the difference in efficiency at average loads gave an annual saving, in the over-all cost of power service for a 2000-ton mine, of $3600. The question of motor-generator sets versus synchronous converters, for mine service, is often decided by factors other then power costs and it is possibly not pertinent to comment at length upon it.

Fuel costs form the major portion of plant operating expenses in all steam-driven plants, hence considerable variations in the cost or quality of coal must of necessity be reflected into rate schedules. In large and medium capacity modern turbo-generator plants the fuel cost is about two-thirds of the total station operating cost, hence, the tendency to higher steam pressures, highest possible vacuum and larger generating units.

It is not difficult, when the average fuel consumption in lb. per delivered kw-hr. is known, to construct an equitable factor for use in a coal cost variant clause, in a rate schedule. Similarly, a correction factor for variations in calorific value of fuel used can easily be worked out. Both provisions are sometimes incorporated in large or long term power contracts and rate schedules. In a recent contract, negotiated by the writer, it was found that the utility was demanding a fuel cost provision which was nearly four times its actual fuel cost increase.

Heretofore, the application of coal cost clauses to rates has been confined to the larger power schedules whose energy costs carried a relatively large portion of fuel expense. A recent departure is noted in the coal clauses filed by the three more important companies in Greater New York, providing for a differential, for all consumers, of 0.05 cents per kw-hr. for each 10 cent change, from $3.00 (average cost in 1916 when present rates were filed) in the cost per ton of coal. It of course, remains to be seen how generally this clause will be filed by other utilities.

The term "fair value", so frequently used in utility valuations for rate determinations, is often difficult to define accurately as a basis. Only that property "used and useful" in the supply of power service is appraised in rate fixing. Rates are often approved or disapproved upon estimates derived principally from operating cost records, as accurate valuations of physical and intangible property require much time and are generally very expensive and the cost must ultimately be borne by the consumers. The subject of valuation and its influence upon power rates is too extensive to form a part of this discussion, but those sufficiently interested can secure a copy of Valuation of Public Utility Properties, by Henry Floy, or Valuation, Depreciation and the Rate-Base, by Grunsky. A comprehensive outline of property accounting is contained in the Classification of Accounts for Electric Companies prescribed by the Public Service Commission of Pennsylvania. A similar classification is used by the Public Utilities Commission of Ohio.

The proper provision in cost accounts and the effect on rate schedules of "depreciation", so extensively discussed in rate problems are barely mentioned. The magnitude of depreciation depends, on the adequacy of prior maintenance and upon customs and individual peculiarities, and it is often an uncertain and somewhat theoretical quantity, but also a factor that should not be ignored or misused. The general subject of rates for electric power service is much too broad to admit of any but brief references to several factors of importance. A copy of Principles of Depreciation, by Salier, will inform you of the distinction between unit, composite and functional depreciation, obsolescence, inadequacy, etc.

It is an interesting fact that only a small part of an enormous public utility debt upon which interest has been defaulted is in electric light and power securities. A recent compilation of approximately $500,000,000, shows that only about $9,100,000, or 1.8 per cent of securities were in bonds of purely electric light and power companies and about $41,278,000 or only 8.25 per cent were in combination railway and electric properties. The fact that during the very de-

cided "seller's market" of the war period, the price of electrical energy has been realtively very low as compared with most any commodity that you may name, is another fact of direct interest to you.

Accurate comparisons of rate schedules with average costs of delivered power will often show that a power company "lives upon and by virtue of its diversity factors."

Induction Motor Nomogram

A Movable Diagram for Reading all Performance Characteristics of any Three-Phase Induction Motor

BY R. G. WARNER
Electrical Engineering Department, Yale University

THE field of the circle diagram, aside from the design standpoint, is the determination of the characteristics of a motor without the necessity of actual loading.

Inasmuch as the full load value of current is quite low on the circle (15 to 20 per cent of its diameter) a large circle is required, of which only a small portion is utilized. Furthermore, a new circle must be drawn for each motor. For these reasons I have constructed a nomogram to depict the performance characteristics of three-phase, 60-cycle motors. This nomogram, Figs. 1 and 2, is based on the simple circle diagram and

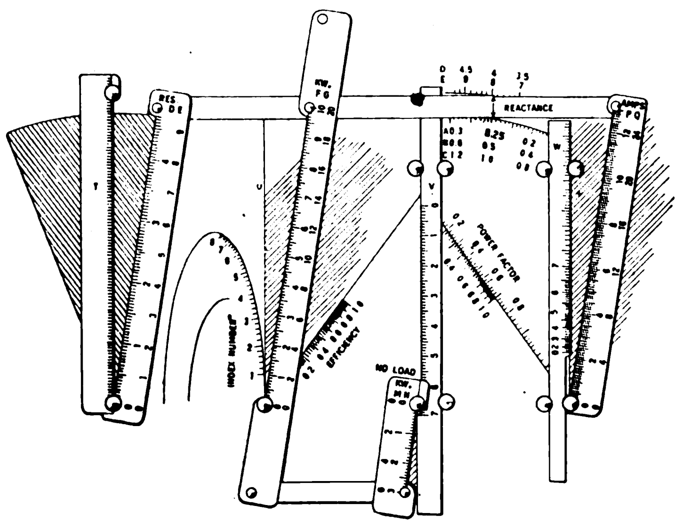

FIG. 1

utilizes the portion for values up to 150 per cent or 200 per cent rated load, depending on the particular motor.

In this nomogram, scales T and U are stationary, scales A to S are pivoted at O and move together and scales V and W slide vertically. The index numbers correspond to points on the circle diagram, any one of which might be chosen to determine values of the characteristics.

REQUIRED MOTOR DATA

The data required to use this nomogram are the same as those required to construct the circle diagram, namely the voltage, current and power for the locked rotor condition and the no-load condition and the primary resistance.

Calculate from the locked rotor values

$$R_e = \frac{W_1 + W_2}{3\,I^2}$$

$$Z_e = \frac{E^2}{3\,I^2}$$

$$X_e = \sqrt{Z_e^2 - R_e^2}$$

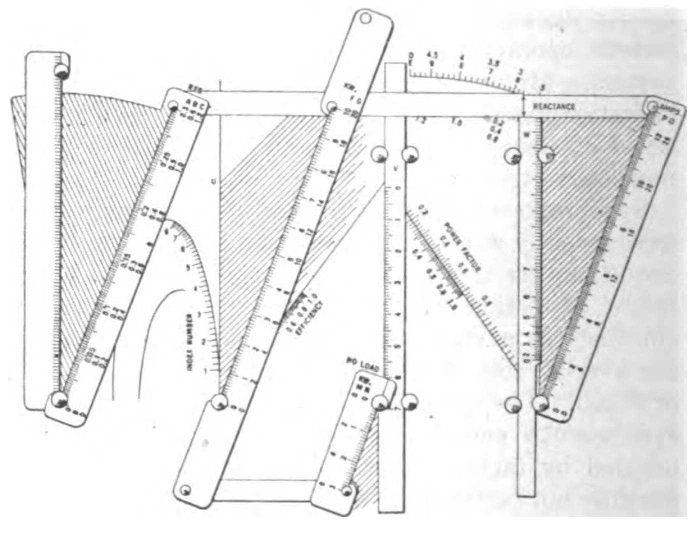

FIG. 2

W_1 and W_2 are the two wattmeter readings as commonly connected for reading the power, I is the current per terminal and E the voltage between terminals.

From the no-load readings, calculate

$$\text{kw.} = \frac{W_{01} + W_{02}}{1000}$$

$$I_0 \sin\theta = \sqrt{I_0^2 - \frac{(W_{01} + W_{02})}{3\,E^2}}$$

The average primary resistance per phase, R_1.

DIRECTIONS

For any particular motor arrange to use for the various quantities the scales as given in the following

table. For example, for a 10-h. p., 220-volt motor, use scales C, G, M and R.

TABLE I

H. P.	Volt	X_e	R_e	Kw.	No-Load Kw.	Amperes
5	110	B	B	F	N	R
5	220	Cx2	Cx2	F	N	Q
5	440	E	E	F	N	P
10	110	A	A	G	M	S
10	220	C	C	G	M	R
10	440	D	D	G	M	Q
20	220	B	B	H	L	S
20	440	Cx2	Cx2	H	L	R
40	440	C	C	I	K	S

For motors of other ratings use scales for the nearest size motor of the same voltage.

Scales D & E are on rear of scales A B C

Scales H & I are on rear of scales F G

Scales K & L are on rear of scales M N

Scales R & S are on rear of scales P Q

1. Set reactance arrow for calculated value of reactance. This will set scales A to S.

2. Set scale V so that 7 on scale V indicates along guide ines to no-load kw.

3. Set scale W so that O indicates along guide lines to I_0 Sin θ on "Amperes."

4. To find torque, from value on T corresponding to primary resistance, project through an index number to U and read value of torque in synchronous watts on kw. scale. To convert this value to pound-feet multiply kw. $\times K/n$ where K is a constant $= 7040$ and n is the synchronous speed of the motor.

5. To find the corresponding output, project from value of R_e on T through the same index number as in 4 to U and read output on kw. scale.

6. To find efficiency, connect point on U (found in 5) to corresponding index number on V and read on efficiency scale.

7. To find power factor, connect index number on V to index number on W and read power factor on black (upper) scale.

8. To find current, project index number on V through power factor on red (lower) scale and read amperes indicated by W along guide lines to current scale.

9. To find speed, calculate

$$\text{speed} = \frac{K\,W}{T}\,n$$

where $K\,W$ is output found in 5, T is torque in synchronous watts found in 4, and n is the synchronous speed.

As many sets of values as desired may be obtained by using various values of the index number.[1]

10. To find the maximum values of torque of a motor, project from resistance value equal to the primary resistance on scale T by means of a tangent to the index number curve to scale U. The maximum torque is read on F, G, H or I in synchronous watts corresponding to point on scale U.

Should this value be beyond the range of the scale a smaller curve is shown directly under the main index number curve. By projecting tangent to this curve the value of torque as read should be doubled.

11. To find the starting torque of the motor, project from value of resistance on scale T corresponding to total resistance to $K\,W$ equal to 0. Using point where this line intersects the index number curve, project from value of resistance equal to primary resistance to scale U and read starting torque in synchronous watts on scales F, G, H or I. As before should this value of synchronous watts be beyond the readable scale the smaller index number curve may be used as stated above.

12. To find the maximum output, project from value of resistance corresponding to total resistance of motor a line tangent to the index number curve to scale U and read corresponding value of output on scales F, G, H or I. Should the value of maximum output be beyond the readable scale the smaller index number curve may be used as above.

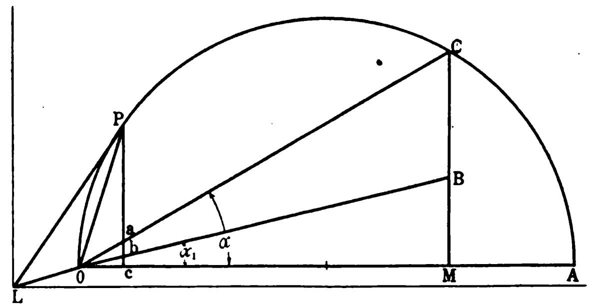

FIG. 3

Basic Construction

The nomogram framework is constructed for a hypothetical induction motor of circle diameter equal to 200 amperes, total reactance equal to 1 and voltage per phase equal to 200. From this the watt scale equals $3\,E_p$ times the I scale, or 1 ampere in phase with the voltage is the equivalent of 600 watts.

The pivoted scales enable one to change from one motor to another when it is desired, and will not be discussed until later. For the present, consider these in the vertical position.

The T scale is actually the ratio of resistance to reactance or the slope of line $O\,C$ in Fig. 3. This ratio is $\tan \angle\, C\,O\,M$, or $\tan\,\alpha$, and $\tan \angle\, B\,O\,M = \tan\,\alpha_1$. This is, however, marked in terms of resistance.

The index number is the actual in-phase component of current of this hypothetical motor divided by 10, or $P\,c$ in Fig. 3.

Scale U is the component of current representing output of this hypothetical motor, or $P\,a$ in Fig. 3.

1. It will be noted that the index number may be chosen for any desired value of output by connecting from value of total resistance to kw. and reading index number.

Scale V is the actual in-phase component of current of this hypothetical motor divided by 10, or $P\,c$ in Fig. 3. When this scale is moved down, a portion is added representing the no-load losses, an amount equal to the in-phase component of $L\,O$.

Scale W is the reactive component of current $O\,c$, but since it has a definite relation to $P\,c$ is labelled in terms of $P\,c$, the index number. When scale W is moved upward a portion is added representing the reactive component of $L\,O$.

When scale W is used with the red (lower) scale of power factor it represents the current $L\,P$.

Relation Between "T" and "U"

The equation of the hypothetical motor in question (assuming the origin at O) has its current locus given by

$$x^2 + y^2 - 200\,x = 0$$

or $y = \sqrt{200\,x - x^2}$

Output $= E\sqrt{200\,x - x^2} - d\,x\,R_e$

where $d = E/x_e =$ diameter

Dividing by E to obtain component of current $P\,a$ (Fig. 3.)

$$P\,a = \sqrt{200\,x - x^2} - x\,R_e/X_e$$
$$= \sqrt{200\,x - x^2} - x\tan\alpha$$

Where

$$\tan\alpha = R_e/X_e$$
$$= \tan\angle\,C\,O\,M$$

This makes an equation of three variables which may be written in a determinant

$$\begin{vmatrix} -1 & a & 1 \\ 1 & b & 1 \\ 1-c & d & 1+c \end{vmatrix} = 0$$

Where $a = \tan\alpha$

$b = P\,a$

$c = x$

$d = \sqrt{200\,x - x^2}$

This may be represented in cartesian coordinates by parametric equations of three curves, corresponding points being given by an intersecting straight line.

(1) $x = -1$ $\quad y = a$

(2) $x = 1$ $\quad y = b$

(3) $x = \dfrac{1-c}{1+c}$ $\quad y = \dfrac{d}{1+c}$

For the results we wish in a motor

a should vary from 0 to 0.7

b should vary from 0 to 70

c should vary from 0 to 30

d should vary from 0 to 70

If plotted to the same scale a would be very small, so we change the scale factors multiplying by factors u_1 and u_2.

(1) $x = -1$ $\quad y = u_1\,a$

(2) $x = 1$ $\quad y = u_2\,b$

(3) $x = \dfrac{u_1 - u_2\,c}{u_1 + u_2\,c}$ $\quad y = \dfrac{u_1\,u_2\,d}{u_1 + u_2\,c}$

Let $u_1 = 100\,u_2$

Curves (1) and (2) will be straight lines.

Curve (3) in parametric form is

$$x = \frac{100 - c}{100 + c} \quad y = \frac{100\,u_2\,d}{100 + c}$$

Curve (1) is represented by scale T and is calibrated in terms of resistance since the reactance is constant and in this case equal to 1.

Curve (2) is represented by scale U.

Curve (3) is the curve marked "Index Number."

The torque, $P\,b$, may be shown by the same curves by using for values of a, $\tan\alpha_1$, since $Pb = \sqrt{200\,x - x^2} - x\tan\alpha_1$.

Relation between U and V

U represents $P\,a$, the output component of current, V (in position) represents $P\,c$ + no-load power component of current, the total power input component of current.

$$\text{Efficiency} = \frac{P\,a}{P\,c + \text{no-load power current}}$$

This again may be expressed in determinants and by parametric equations of three straight lines, of which $P\,a$ (U) and $P\,c$ (V) are regular. The efficiency scale is plotted for distance from a point 0, where efficiency is marked 1, to -1 where efficiency is marked 0 according to the function

$$\text{Distance} = \frac{\text{efficiency} - 1}{\text{efficiency} + 1}$$

Relation between V and W

Scale V (in position) represents the power component of current $P\,c$ + no-load power component of current, and W (in position) represents the reactive component of current $O\,c$ + reactive component of $L\,O$.

The (upper) scale marked power factor is plotted for distances from $+1$ where power factor $= 0$ to -1 where power factor $= 100$ per cent according to the function

$$\text{Distance} = \frac{\tan\theta - 1}{\tan\theta + 1}$$

Instead of being marked in terms of $\tan\theta$, the scale is marked in terms of the corresponding power factor.

The (lower) scale marked power factor is plotted for distances from -1 where power factor $= 0$ to 0 where power factor $= 100$ per cent according to the function

$$\text{Distance} = \frac{\cos\theta - 1}{\cos\theta + 1}$$

In this case

$$\text{Cos}\,\theta = \frac{P\,c}{O\,P} = \frac{V}{W}$$

or when V and W are moved to add the components of $L\,O$

$$\text{Cos}\,\theta = \frac{P\,a + \text{power component of } L\,O}{L\,P}$$

CHANGE OF X_e

When we change from one motor to another of the same voltage the effective reactance will change. Now let us consider that our hypothetical motor had a maximum ordinate of 100 per cent rather than 100 amperes, and that our index number represents per cent instead of amperes. Then point 3 will represent 30 per cent of the maximum ordinate.

Choose a new motor for the same voltage which would have a total reactance of say 0.5. This would represent a motor of approximately twice the capacity of the first. Our new diameter $O\,A$, Fig. 3, would represent $\frac{200}{0.5}$ or 400 amperes. Now point 3 representing 30 per cent of the maximum ordinate is equivalent to 60 amperes. Since the kw. per ampere is dependent only on the voltage, the scale readings of watts and

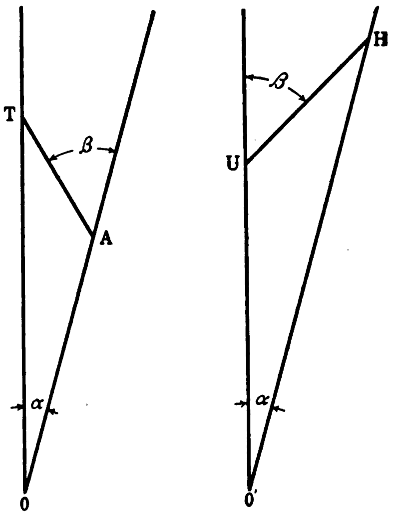

FIG. 4

amperes should be increased proportionally. This is done by moving scales H to S inclusive by the same angle, and by the law of similar triangles the ratio is the same (see Fig. 1). These are moved, so that referring to Fig. 4

$$\frac{O'\,U}{O'\,H} = \frac{X_e}{1} \text{ where the basic } X_e = 1$$

The T scale is a ratio of resistance to reactance, hence as the reactance is reduced the resistance must be reduced proportionally to have the same ratio at a given point. This is done by changing the angle of the guide lines with the scale of resistance. Referring to Fig. 4, T and U are stationary and A and H move together so that angle $T\,O\,A$ is always equal to angle $U\,O'\,H$. Angle $O\,A\,T$ is constant and equal to angle $O'\,U\,H$. Hence by similar triangles

$$\frac{O\,A}{O\,T} = \frac{O'\,U}{O'\,H}$$

$$\text{but } \frac{O'\,U}{O'\,H} = \frac{X_e}{1}$$

As T represents actually the ratio of resistance to reactance, if the reactance is decreased then the resistance should be decreased proportionally, which is done, since

$$\frac{O\,A}{O\,T} = \frac{X_e}{1}$$

CHANGE OF VOLTAGE

When the voltage is changed and the reactance kept constant, the diameter, $\frac{E}{X_e}$ is changed proportionally. Suppose the voltage to be doubled, then the diameter is doubled and the watts per ampere are doubled.

Again, point 3, or 30 per cent of the maximum ordinate, will represent 60 amperes, and as the watts per ampere are doubled this will represent four times as many watts. As the commercial voltages change in very definite steps, usually doubling, this change of voltage is taken care of in general by changing scales by multiples of 2.

As the resistance scale is actually a ratio to reactance this does not change due to voltage alone.

CHANGE OF RATING—VOLTAGE CONSTANT

Changing from one set of scales to another was described under changes of voltage. This may equally well be required under change of reactance. For example, two motors of the same voltage but of considerably different reactance will have considerable difference in rating, *i. e.* a 5-h. p., 220-volt motor would have approximately twice the reactance of a 10-h. p., 220-volt motor. It is better, then, in changing from a 5 to a 10-h. p. motor, to change scales. Change the reactance scale to one of one-half the value. Inasmuch as the current scale represents per cent of maximum ordinate and the maximum ordinate is doubled, the current scale should be doubled. As the watts per ampere for a given voltage are constant the watt scale must be doubled. As the resistance is actually a ratio to the reactance it must be changed to a scale corresponding to the reactance.

CHANGE OF VOLTAGE RATING

If two motors of the same horse power rating are considered, but one is rated at one-half the voltage of the second, it is again necessary to change the scales. For a given rating, if the voltage is doubled the current is halved, consequently the diameter of the circle, $\frac{E}{X_e}$, is one-fourth. We then change to a reactance scale of one-fourth value. As the maximum ordinate is one-half, the current scale should be one-half. As the watts per ampere are doubled, the watt scale should be the same. The resistance scale as before should be changed to correspond to the reactance scale.

Present Scales

Values for the present sets of scales are chosen to give the expected values for motors from 5 to 25 h. p. The kw. scale is the basic scale. Referring to the scale D, 7 kw. represents 70 per cent of the maximum ordinate of the circle. For 110 volts then the maximum ordinate in amperes would be 52.5 per phase. The reactance per phase would be

$$X_e = \frac{E_p}{52.5 \times 2} = 0.605$$

This in turn determines the resistance scale. Other scales are actually multiples of this set.

New Scales

From the previous discussion I believe it is possible to construct new scales as in the following. To use the nomogram for an 800-h. p., 2200-volt, three-phase, 60-cycle, 350-rev. per min. induction motor: The short-circuit characteristic gives the following data:

$$R_e = \frac{655.000}{3 \times 900^2} = 0.269$$

$$R_1 = 0.1893$$

$$X_e = \sqrt{\left(\frac{1270}{900}\right)^2 - 0.269^2} = 1.358$$

Watts per ampere

$$2200 \times \sqrt{3} = 3.81 \text{ kw.}$$

Max. ordinate

$$\frac{E}{2\,X_e} = \frac{1270}{2.770} = 459 \text{ amperes}$$

$$459 \times 3.81 = 1750 \text{ kw.}$$

0.3 Max. ordinate, $459 \times 0.3 =$ 138 amperes
$1750 \times 0.3 =$ 525 amperes

It will be noticed that $X_e = 1.385$ may be determined on scale C times 2 or scale D divided by 2. Referring to Table of Scales, page 809, scale C times 2 is used with F, N, Q, for a 5-h. p., 220-volt motor. It will be noted that this is applicable to the motor in question if the scale of amperes is multiplied by 10 and the kw. scale by 100 to account for the different voltages.

Example

By running the motor light at normal voltage it is found:

$I_0 = 66.4$
$W_0 = 21.6$ kw.

and power factor

$= 8.56$ per cent

Proceed as follows: (See Fig. 2)

Set reactance to indicate 1.385 on scale $C \times 2$ or scale D divided by 2

Set scale V to indicate 21.6 kw. on scale $N \times 100$

Set scale W to indicate 66 amperes on scale $Q \times 10$

Read as follows for full load:

From Res. = 0.269 on scale $C \times 2$ as indicated on T read to 597 kw. as indicated by scale F on U and read index number 3.65.

From 597 kw. to index number 3.65 on scale V and read efficiency 0.93.

From index number 3.65 on scale V to index number 3.65 on scale W and read power factor 0.88.

From index number 3.65 on scale V through power factor (lower scale) equal to 0.88 read current per terminal on scale $Q \times 100$ (as indicated on W) 194 amperes. For torque, from Res. = 0.189 as indicated by scale $C \times 2$ on T through index number 3.65 read on scale $F \times 100$ (as indicated on U) 602 synchronous kw.

$$= \text{Slip} = \frac{602 - 595}{602}$$

$$= \frac{7}{602} = 1 + \text{per cent}$$

Maximum output is obtained by projecting from Res. = 0.269 on scale T tangent to smaller index number curve and reading on scale $F \times 200$, 1300 kw. (as indicated on U). Similarly maximum torque is read by projecting from resistance = 0.189 tangent to index curve and reading 1480 kw. synchronous torque on scale $F \times 200$ as indicated on U.

Starting torque is found as 180 kw. synchronous torque by projecting from resistance = 0.269 to zero kw. and through point thus found on index curve projecting from resistance equal to 0.189 to scale U reading on scale F.

The following is descriptive of the methods used in constructing various portions of the nomogram.

Index Number Scale

Preliminary sketches of the curve on which the index number scale appears, indicated a curve which approximated a circle with certain scale factors. As a circle is more easily drawn than most curves the equation of the circle was obtained as follows.

In parametric form (see p. 810):

$$x = \frac{u_1 - u_2\,c}{u_1 + u_2\,c} \tag{1}$$

$$y = \frac{u_1\,u_2\,d}{u_1 + u_2\,c} \tag{2}$$

Eliminating c and d

$$\begin{aligned} c &= x_1\,d \\ &= \sqrt{200\,x_1 - x_1^2} \\ &= \sqrt{200\,c - c^2} \end{aligned} \tag{3}$$

From (1)

$$\begin{aligned} x\,u_1 + x\,u_2\,c &= u_1 - u_2\,c \\ c\,u_2\,(x+1) &= u_1\,(1-x) \\ c &= \frac{u_1}{u_2}\,\frac{1-x}{1+x} \end{aligned}$$

Substituting in (3)

$$d = \sqrt{\frac{200\,u_1\,(1-x)}{u_2\,(1+x)} + \frac{u_1^2\,(1-x)^2}{u_2^2\,(1+x)^2}}$$

$$= \frac{1}{u_2\,(1+x)}\sqrt{200\,u_1\,u_2\,(1-x^2) - u_1^2\,(1-x)^2}$$

From (2)

$$y\, u_1 + y\, u_2\, c = u_1\, u_2\, d$$

$$y\, u_1 (1 + x) + y\, u_1 (1 - x) = \mu\, 1 \sqrt{200\, u_1\, u_2 (1 - x^2) - u_1^2 (1 - x)^2}$$

$$(2\, y)^2 = 200\, u_1\, u_2 (1 - x^2) - u_1^2 (1 - x)^2$$

$$4\, y^2 = -\,200\, u_1\, u_2\, x^2 - u_1^2\, x^2 + 2\, u_1^2\, x + 200\, u_1\, u_2 - u_1^2$$

$$x^2 (u_1^2 + 200\, u_1\, u_2) + 4\, y^2 - 2\, u_1^2\, x - 200\, u_1\, u_2 + u_1^2 = 0$$

$$x^2 - \frac{2\, u_1^2}{u_1^2 + 200\, u_1\, u_2} + \frac{4\, y^2}{u_1^2 + 200\, u_1\, u_2} + \frac{u_1^2 - 200\, u_1\, u_2}{u_1^2 + 200\, u_1\, u_2} = 0$$

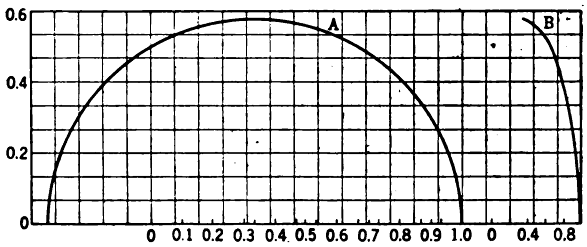

Fig. 5—Index Scale Construction

This is the equation of a circle if scales are chosen such that

$$u_1^2 + 200\, u_1\, u_2 = 4$$

In this case the center is at

$$y = 0$$

$$x = \frac{u_1}{u_1 + 200\, u_2}$$

$$\text{Radius} = -\,\frac{u_1 - 200\, u_2}{u_1 + 200\, u_2} + \frac{u_1}{(u_1 + 200\, u_2)}$$

$$\text{Radius} = \frac{200\, u_2}{u_1 + 200\, u_2}$$

$$\text{When } u_1 = 100\, u_2$$

$$\text{Center becomes} = \frac{u_1}{u_1 + 2\, u_1} = \frac{1}{3}$$

$$\text{Radius} = \frac{2\, u_1}{u_1 + 2\, u_1} = \frac{2}{3}$$

Ratio of x to y scale

$$u_1^2 + 2\, u_1^2 = 4$$

$$3\, u_1^2 = 4$$

$$u_1 = \frac{2}{\sqrt{3}} = 1.154$$

$$\frac{1}{u} = 0.86$$

This circle was drawn to scale so that the ordinate was correct for the nomogram, curve A, Fig. 5. The abscissa was then reduced to correct scale for nomogram and the curve B drawn and was then readily transferred to the nomogram.

Since, with resistance zero, the index number equals the ordinate, the index number scale was divided by connecting point res. = 0 to various points on watt scale and marking the index scale accordingly.

Reactance Scale

Referring to Fig. 6B,

$$O\, b = \frac{O\, c}{\text{Cos}\,(\alpha + 90 - B)}$$

$$O\, a = \frac{O\, c}{\text{Cos}\,(90 - B)}$$

$$\frac{O\, b}{O\, a} = \frac{\text{Cos}\,(90 - B) + X_a}{\text{Cos}\,(\alpha + 90 - B)\, X_b}$$

Where X_a is the reactance corresponding to $O\,a$
and X_b is the reactance corresponding to $O\,b$
B is 45 degrees

$$\frac{O\, b}{O\, a} = \frac{1}{\text{Cos}\,(\alpha + 45)} = \frac{1}{\text{Cos}\,\alpha - \text{Sin}\,\alpha} = \frac{X_a}{X_b}$$

$$\text{or } X_b = X_a\,(\text{Cos}\,\alpha - \text{Sin}\,\alpha)$$

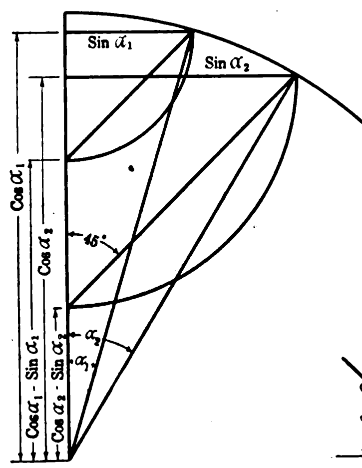

Fig. 6A

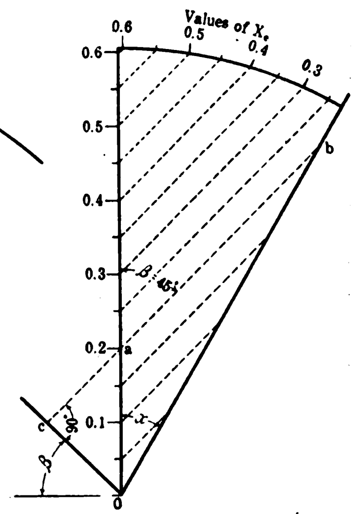

Fig. 6B

Cos α – Sin α may be graphically constructed by means of a compass as shown in Fig. 6A. Another method of obtaining the same result is by means of a 45-deg. line from the extremity of the radius which is rotated through some angle α, Fig. 6A. This leads to the construction shown in Fig. 6B. A temporary vertical scale of reactance was used and its values were projected by 45-deg. guide lines to determine the permanent scale of reactance. It is marked the same as the value of the temporary scale, which is

$$X_a\,(\text{Cos}\,\alpha - \text{Sin}\,\alpha)$$

Other Scales

All of the moving scales were marked by a dividing engine. The desired distances between divisions were calculated and tabulated in millimeters in advance.

The fixed scales of efficiency and power factor were divided by connecting two points of the desired ratio and marking accordingly. In general 10 or 5 was chosen for the denominator of the ratio.

A large amount of the basic nomographical methods used has been obtained from material which will be published in Professor H. L. Seward's "Construction of Permanent Diagrams for Engineering Formulae."

CORRESPONDENCE

DEVELOPMENT OF THE CIRCLE DIAGRAM

To the Editor:

The writer's article published in the May 1920 JOURNAL, page 458, entitled *Theory of Speed and Power Factor Control of Large Induction Motors by Neutralized Polyphase Alternating Current Commutator Machines* contained the following reference note:

For the development of the circle diagram, particular mention should be made of the works of Behrend, Blondel and Arnold-la Cour. Meyer-Delius has also written concerning what the writer has termed single-range regulation.

This note gave insufficient detail, resulting in the impression that originality was claimed for more of the ideas than were actually new. The writer therefore wishes to state that diagrams like Fig. 6, Fig. 9 and Fig. 11 were developed by Dr. H. Meyer-Delius and published in *Electrotechnische Zeitschrift*, May 1913, page 496, the article referred to in the above reference note.

The writer has later been informed by Dr. Meyer-Delius that the latter had also prepared, but not published, a diagram like Fig. 13.

The works of Alexander Heyland should also be mentioned for the development of the circle diagram.

The writer regrets any injustice done by the brevity of the former reference note and hopes the above will correct any existing wrong impression.

JOHN I. HULL

EDDY CURRENT LOSSES—A CORRECTION

To the Editor:

In attempting to apply the formulas of my article entitled *Tooth Frequency Losses in Rotating Machines*, which appeared in the A. I. E. E. JOURNAL, September 1921, to actual machines, it was noted that formula 4, page 755, for the tooth pulsation eddy current loss gave values much too low. The original calculations were then checked and a numerical error was found which altogether alters the conclusions in regard to the magnitude of the eddy current losses. The constant in this formula should be 1.3×10^{-7} instead of 1.96×10^{-9}. This makes the calculated eddy loss in the example, page 756, equal to 25.2 watts instead of 0.38. Therefore under the assumed conditions the eddy current loss due to the tooth pulsations is approximately equal to the total fundamental losses plus the tooth-pulsation hysteresis loss. In other words, for 17-mil sheet the tooth pulsation eddy current losses are as we have found by actual tests a large percentage of the total pulsation losses instead of being negligible as previously stated. The writer greatly regrets this error and trusts that you will call it to the attention of your readers in order that those who attempt to use this formula will not be led astray.

THOMAS SPOONER
Westinghouse Electric & Mfg. Co.

TELEGRAPH AND TELEPHONE NOTES

The wide extension of amateur and experimental radio installations throughout the country, together with the probable widespread use of radio telephone stations for Broadcast service, has prompted the compilers of the National Electric Code to incorporate in that publication revised rules to meet the changing conditions. The Standardization Committee of the Institute of Radio Engineers, New York, now has in hand the framing of a set of regulations to be recommended for inclusion in the next edition of the Code.

The telegraph and telephone section, American Railroad Association, has up with the Secretary of Commerce, Washington, the matter of securing modification of the regulation that telegraphers operating radio telegraph transmitting stations must use the Continental alphabet. In the near future several railroads expect to employ radio in the handling of message traffic, where the system can be used to advantage, and it is desired that telegraphers already in the service of the railroads and who use only the American Morse code be permitted to operate the stations without having to learn the Continental alphabet. The American Morse code is used on all land line systems in the United States and Canada. J. D. Jones, superintendent of telegraph, Pennsylvania Railroad, Philadelphia, is chairman of the A. R. A., committee.

Short-distance printing telegraph systems are now successfully applied in a number of industrial plants to meet modern requirements of internal communication. Systems now available are simple, economical and reliable.

A. I. E. E. NOVEMBER MEETING
JOINT SESSION WITH THE SOCIETY OF NAVAL ARCHITECTS AND MARINE ENGINEERS

The 372d meeting of the Institute will be held in the Engineering Societies Building on Thursday, November 17, 1921. The meeting will consist of an afternoon and an evening session.

The afternoon session will be a joint session with the Society of Naval Architects and Marine Engineers, forming a part of the annual meeting of that society. Two papers will be presented at this session as follows:

Electric Auxiliaries, by E. D. Dickinson, Marine department of the General Electric Co.

Electric Propulsion, by W. E. Thau, Commerical Engineer of the Westinghouse Electric and Mfg. Co.

The paper by Mr. Dickinson is printed elsewhere in this issue of the JOURNAL.

The evening session will be devoted to a lecture on *World Communication*, by Alfred N. Goldsmith, Professor of Electrical Engineering, City College of New York.

NEW YORK SECTION MEETING
October 19, 1921

The first N. Y. Section meeting for the new administrative year will be held in the Auditorium of the Engineering Societies Building, 33 West 39th Street, New York on Wednesday evening, October 19th. This will be a joint meeting with the New York Sections of the A. S. M. E., the A. S. C. E., and the A. I. M. E. The subject to be discussed will be "Engineering Financing" and while it is impossible at the present time to announce the speaker's names, every effort is being made to obtain men of particular prominence in this field. A detailed announcement will be mailed to the membership as soon as possible.

The complete schedule of N. Y. Section meetings for the year follows.

1. Engineering Financing, October 19, 1921.
2. The Great Lakes, St. Lawrence Canal, November 14th, 1921.
3. Central Station Operating, December 14th, 1921.
4. Industrial Power Requirements, January 27th, 1922.
5. The Port of New York, March 15, 1922.
6. (Subject to be announced later), April 19, 1922.

PHILADELPHIA SECTION MEETING
OCTOBER 10, 1921

The first scheduled meeting this season of the Philadelphia Section of the A. I. E. E. will be held on October 10th at the Engineers Club, 1317 Spruce Street, Philadelphia. The speaker will be Mr. Frank B. Gilbreth and the subject, "One Best Way to do Work."

The Philadelphia Section cordially invites the attendance of members of adjoining Sections.

ENGINEERING FOUNDATION

A regular meeting of Engineering Foundation was held September 8 at which several research projects were discussed as follows:

Fatigue of Metals. Correspondence with the University of Illinois, Engineering Experiment Station, was submitted. It was stated that the complete report on the research, in manuscript form, had been sent to the office of the Division of Engineering, National Research Council, and would within a few days, be delivered to Engineering Foundation office. On suggestion of Chairman Rand, it was voted that the manuscript of the report on Fatigue of Metals research, drafted by the Engineering Experiment Station, University of Illinois, and approved by the Advisory Committee of National Research Council be referred to Dr. Goss for examination and advice as to approval on behalf of Engineering Foundation.

Steam Tables. Communication dated July 30 from American Society of Mechanical Engineers, requested assistance of Engineering Foundation in a "research for determining constants for the upper limits of steam tables." Chairman Arthur M. Greene, Jr., of the Society's research committee, gave information concerning the need, plans and anticipated support for the proposed research and suggested a modest contribution to be spread over three years. It was voted that Engineering Foundation contribute toward expenses for research for determining constants for the upper limits of steam tables, under the auspices of the American Society of Mechanical Engineers, and that Dr. D. S. Jacobus represent Engineering Foundation in the conduct of the Steam Tables research.

Graphitic Corrosion of Cast Iron. Mr. J. Vipond Davies described deterioration of cast iron exposed to salt or brackish water, or buried in soils impregnated with certain salts or acids, by which the character of the castings in part or whole is changed from that of metallic iron to that of graphite, which can be readily cut with a knife. He suggested the name "Graphitic Corrosion" for this form of deterioration, and stated that it had been known for many years, was not understood, and affected water and gas pipes, pumps and condensers of steam plants parts of sea-going vessels, and other objects. It was constantly causing loss and danger, and was doubtless the cause of much damage attributed to electrolysis by stray currents. He had been studying the problem for twelve years, or more, in the interest of clients, with the aid of numerous experts, but with small increase of knowledge. Because of the importance to many industries and engineers, he suggested a comprehensive

research by Engineering Foundation and offered to cooperate by making available results of his own investigations. Mr. Moultrop and the Secretary told also of their experiences along these lines. It was referred to Executive Committee for study and recommendation.

EMPLOYMENT SERVICE

The employment service which the Institute has maintained for many years and which since January 1921, has been conducted under the auspices of the Federated American Engineering Societies has been making great efforts during the present year to aid in the solution of the employment problem in the engineering field.

With 1500 unemployed engineers registered at the Bureau's headquarters, 33 West 39th Street, New York, men of many degrees of experience, from the most recent graduate to the high salaried executive, it was early recognized by the Management Board that, in addition to the regular systematic routine of operation, the Bureau must adopt special measures to cope with the situation and with this end in view an additional appropriation was asked and obtained from the Federation. Members of the Institute are earnestly requested to advise the Bureau of openings within their own organization or of outside opportunities of which they may know. Particular emphasis is laid upon the many advantages to the employer of dealing with the Federation Bureau, the large number of men with whom the Bureau is in touch, the comprehensive classification of educational and professional records, available, and the fact that the services of the Bureau are free.

A Volunteer Committee, composed of engineers registered with the Bureau, was organized early in the summer and undertook at their own expense the task of having the attention of every employer of engineers in New York City called to the available facilities of the Engineering Bureau, through one or more personal visits. This work was so systematically laid out that there was no duplication of effort, no possibilities overlooked and the results were tabulated for present and future use. Up to August 12th, the calls made amounted to 1623 and the interviews granted 1009, resulting in 36 opportunities for employment and 59 prospective positions. This work has been in progress in New York since before June 1st and is now nearing an end. It is hoped to have a similar canvas carried on in other large cities.

Through the campaign, as outlined, it is expected that the scope of the Bureau will be greatly increased and with that increased scope will come its ability to be of even greater service to members of the Engineering Societies in the future than it has been in the past.

PERSONAL MENTION

W. M. Brown formerly Electrician with the Martinez Electric Co., is now Electrician with the Union Pacific Coal Co.

T. H. McWhirk who was with the General Electric Co. at Atlanta, is now Chief Electrician aboard the U. S. S. *Maryland*.

William G. Dow formerly of the Industrial Sales Department, Westinghouse Electric & Manufacturing Co., is now Testing Engineer, Commonwealth Edison Co., Chicago, Ill.

W. D. Cannon formerly Research Graduate Assistant, University of Illinois, is now Engineering Assistant, Western Union Telegraph Co., 195 Broadway, New York.

F. P. Townsend has severed his connection as electrical engineer, Submarine Boat Corporation, and is now connected with the Kindred Appliances Co., 39 Cortlandt Street, New York.

E. E. Perkins, Jr., formerly of the Carroll Electric Co., has been appointed assistant instructor in electrical engineering at the University of Illinois, Urbana, Ill.

F. S. Bird formerly General Superintendent, Texas Construction Co., is now with the Oil Belt Power Co. at Eastland, Texas.

Cecil L. Eaton who was Assistant Superintendent, Joseph Meyer, Inc., is now Salesman with the Shiff Auto Supply Co., Box 547, Orlando, Fla.

G. B. Burnham formerly Manager, Burnham Chemical Co., is now Technical Director of the company, with offices at 1016 Hobart Building, San Francisco, Cal.

H. L. Burgess has left the New York office of the American Telephone and Telegraph Co., and is now with the Bell Telephone Co. of Pennsylvania, office 1631 Arch Street, Philadelphia, Pa.

Howard W. Mott has left the Western Electric Co.nd is a now in charge of instruction in electrical engineering at Stuyvesant High School, 345 East 15th Street, New York.

J. E. Cannell formerly Electrical Engineer with Reeds & Thorpe, is now with J. J. Cannell, Electrical Contractor, 20 Chelsea Street, Everett, Mass.

Walter J. Berry has left his position of Operating Engineer for the Hotel Bossert and is now a Salesman with the Superheater & Engineering Co., Room 1816 Woolworth Building, New York.

Earl M. Newlin formerly Assistant Engineer, Superpower Survey, is now connected with Goodwin, Newlin & Co., 133 South 12th Street, Philadelphia, Pa.

J. H. McClure formerly Vice-President, The Ohio Electric Railway Co., is now with the Indiana, Columbus & Eastern Traction Co., Interurban Building, Springfield, Ohio.

A. D. Hecker who was electrical foreman with the American International Shipbuilding Corporation, is now electrician with the Arrow Electric Co., Philadelphia, Pa.

John E. Breese formerly with the Western States Gas & Electric Co., is now draftsman with the Solar Refining Co. Lima, Ohio.

Carl J. Koch formerly Instruction Supervisor, Extension Division, School of Engineering of Milwaukee, is now Switchboard Engineer with the Western Electric Co. of Chicago.

Albert E. Pierce previously Secretary of Blodgett, Hart & Co., is now Vice-President, Harvey Fisk & Sons, 105 South La Salle Street, Chicago, Ill.

R. H. Spring previously Assistant to the Field Electrical Engineer, American Railways Co., is now Manager, Cape May Light & Power Co., Cape May City, N. J.

Lloyd P. Joubert formerly Draftsman with the Todd Dry Dock & Construction Corporation, is now Electrical Engineer, C ty of Takoma Lighting Department, City Hall, Takoma, Wash.

Richard H. Olson a former partner in the firm of Pearson & Olson, is now Sales Engineer with the Electrical Machinery Manufacturing Co., Minneapolis, Minn.

T. B. Pierce formerly President, Kentucky West Virginia Engineering & Electric Co., is now President and General Manager of the Central Electric Co., Huntington, W. Va.

Geo. F. Whitworth formerly Assistant Engineer with the Pacific Gas & Electric Co. is now with the University of California, Berkeley, Cal.

Chas. C. Snyder formerly Distributor, Westinghouse Batteries, is now Manager, Los Angeles Branch of the Coast Equipment Co., Los Angeles, Cal.

A. W. Lynch formerly Superintendent, Water and Light Department of Forest City, N. C., is now Sales Engineer, Piedmont Electric Co., Ashville, N. C.

J. C. Lawler previously Purchasing Department, Great Western Sugar Co. of Denver, is now Manager of the "J-E" Battery Co. of Southern California, Los Angeles, Cal.

W. J. Timmins formerly Assistant Chief of Research Laboratory, Edison Storage Battery Co., is now Construction Engineer with Pewick Bros., Des Moines, Iowa.

R. W. Robinson formerly Chief Operator, Nevada-California Power Co. at Goldfield, is now Construction Engineer with Thomas H. Ince Studios, Culver City, Cal.

John H. McDonnell is now a partner in the firm of Benneche & McDonnell, Electrical Engineers and Contractors, Marion, Ohio.

T. Miwa has opened an office as Consulting Engineer, 1909 Bush Street, San Francisco, Cal. Mr. Miwa was formerly Superintendent of the California Vegetable Packing Co., Ltd., of Los Angeles.

Frank P. Boone formerly Electrical Engineer with the United States Food Products Corporation, is now Superintendent, Meter Department, Southern Illinois Light & Power Co., 902 Central National Bank Building, St. Louis, Mo.

Alex. J. MacAllister formerly Assistant Mechanical Engineer, American Smelting & Refining Co., is now Student Engineer with the Southern California Telephone Co., 716 Olive Street, Los Angeles, Cal.

R. H. Wheeler has left his position as Assistant Construction Manager with Dwight P. Robinson & Co., Inc., and is now General Manager, Western New York & Pennsylvania Traction Co., 142 N. Union Street, Olean, N. Y.

Charles D. Kunkel has accepted position of Power Apparatus Specialist with the Western Electric Co., Los Angeles, Cal. He was formerly Sales Engineer with the Westinghouse Electric & Manufacturing Co. at San Diego.

Marshall J. Maxfield formerly instructor in Electrical Engineering at Pennsylvania State College, has accepted the position of Director of Laboratory Instruction, Department of Industrial Engineering, Pratt Institute, Brooklyn, N. Y.

Arsene Rivero formerly in the Transformer Drafting Department, Westinghouse Electric & Manufacturing Co., is now in the Engineering Department of the New York Edison Co., at Irving Place.

C. T. Wilkinson, Milliken Manufacturing Syndicate, London, announces the award to the New York house of a contract for the construction of a 112 mile, 132,000-volt transmission line to carry power from Victoria Falls to Melbourne, Australia.

C. H. Sexton formerly Operating Manager, Hattiesburg Hattiesburg Creosoting Co., has just been appointed General Manager of the Southern Paving Construction Co., Pensacola, Fla.

Hobart H. Newell formerly of the Research Laboratory, Westinghouse Electric & Manufacturing Co. is now in the Electrical Engineering Department of Worcester Polytechnic Institute, Worcester, Mass.

L. P. Dickinson who was professor of Electrical Engineering at Robert College, Constantinople, has been appointed Head of the Department of Electrical Engineering in the University of Vermont.

S. W. Fleming, Jr., of the firm of Gannett, Seelye & Fleming, Inc., has been appointed by Governor Sproul of Pennsylvania a member of the Commission to mark the battle fields of France and Belgium where Pennsylvania units fought.

Burt K. Spenser formerly Electrical Engineer with A. C. Wood of Philadelphia, is now directing the underwriting of a new line of insurance covering indemnity against burnout or breakdown of electrical apparatus for the Travelers Indemnity Company, Hartford, Conn.

W. E. Freeman formerly Supervisor of Commercial Training, Westinghouse Electric & Manufacturing Co., has been appointed Acting Dean of the University of Kentucky. Dean Anderson will also direct the work of the Research Laboratory of the American Society of Heating and Ventilating Engineers in the Bureau of Mines, Pittsburgh, Pa.

Lewis L. Ransom has resigned as Treasurer and Manager of the Bayonne branch of John R. Proctor, Inc., and is now connected with the Ransom and Anderson Co., Inc., Designing and Constructing Engineers, with offices at 136 Liberty Street, New York City, and 75 Montgomery Street, Jersey City, N. J., as Vice-President and Treasurer.

OBITUARY

Charles W. Davis, vice president and general sales manager of the Standard Underground Cable Co., Pittsburgh, Pa., died Sunday, September 11 in the Memorial Hospital, New York. He had been in failing health for several years and had gone to New York for special medical treatment. Mr. Davis was born in Pittsburgh 48 years ago and was educated at the Western University of Pennsylvania, now the University of Pittsburgh, and at the M. I. T. His connection with the Standard Underground Cable Co. began shortly after his graduation from college, or about 1899, at which time he was employed by the company as construction engineer on a large cable installation in Mexico City. Later he became Superintendent of Construction and Manager of the Central Sales Department. In 1915 he was elected Vice President in charge of the General Sales, Construction and Accessories Departments. He was well-known in the electrical industry as an expert on the design, manufacture and installation of electric cables and accessories, and had contributed largely to the development of the art by his investigations, technical papers and inventions. He had been an Associate in the A. I. E. E. since 1907.

James A. Walton, Electrical Engineering Department, Edison Electric Illuminating Company of Boston died on August 14th, 1921. Mr. Walton was born in Cambridge, Mass. in 1885. He took the electrical course at Lowell Institute. He was assistant in the electrical laboratory at the M. I. T., later went with the Consolidated Gas & Electric Light & Power Co. of Baltimore and finally with the Edison Co. of Boston in the Engineering Department. Mr. Walton joined the A. I. E. E. in 1909 and was transferred to the grade of Member in 1913.

Peter Cooper Hewitt famous scientist and inventor died on August 25, 1921 at the American Hospital, Paris, from pneumonia following an operation. He was born in New York in 1861, a son of Mayor Abram S. Hewitt of New York and grandson of the philanthropist, Peter Cooper. He was educated at Stevens Institute of Technology and received the honorary degree of Sc. D. from Columbia University in 1903 and from Rutgers College in 1916. Mr. Hewitt was probably best known through his invention and development of the mercury vapor lamp which bears his name, although the range of his efforts was extraordinary, for he accomplished results in the widely different fields of economics, physics, mechanics, chemistry, and electricity. He perfected apparatus for the wireless telegraph and telephone field, for aerating liquids, centrifugal separators, and was a pioneer in hydro-airplane and high-speed motor boat development. He was a director of the N. Y. & Greenwood Lake Ry., Cooper Hewitt & Co., Midvale Water Co. and many others. He was a Vice President of the Naval Consulting Board and a member of numerous clubs and societies among which which may be mentioned the Engineers, Players, Lambs, Union and Knickerbocker Clubs; the Society of Automotive Engineers, the Franco-American Commission, Aero Club of America, etc. Mr. Hewitt was elected to the Institute as an Associate in 1901 and was transferred to the grade of Member in 1907.

ENGINEERING SOCIETIES LIBRARY

The library is a cooperative activity of the American Institute of Electrical Engineers, the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers and the American Society of Mechanical Engineers. It is administered for these Founder Societies by the United Engineering Society, as a public reference library of engineering and the allied sciences. It contains 150,000 volumes and pamphlets and receives currently most of the important periodicals in its field. It is housed in the Engineering Societies Building, 29 West Thirty-ninth St., New York.

In order to place the resources of the Library at the disposal of those unable to visit it in person, the Library is prepared to furnish lists of references to engineering subjects, copies or translations of articles, and similar assistance. Charges sufficient to cover the cost of this work are made.

The Director of the Library will gladly give information concerning charges for the various kinds of service to those interested. In asking for information, letters should be made as definite as possible, so that the investigator may understand clearly what is desired.

The library is open from 9 a. m. to 10 p. m. on all week days except holidays throughout the year except during July and August when the hours are 9 a. m. to 6 p. m.

BOOK NOTICES (AUG. 1-31, 1921)

Unless otherwise specified, books in this list have been presented by the publishers. The Society does not assume responsibility for any statements made; these are taken from the preface or the text of the book.

All the books listed may be consulted in the Engineering Societies Library.

The A. B. C. of Iron and Steel

Edited by A. O. Backert. Cleveland Penton Publ. Co., 1921. 408 pp., illus., 11 x 8 in., cloth. $5.00.

This is a simple, concise yet comprehensive account of the primary processes involved in the conversion of iron ore into finished products, intended for general readers who wish a knowledge of these processes, and for technical readers wishing general information on phases of the industry outside their own experience. The book is elaborately illustrated.

Broaching Practise.

By E. K. Hammond. N. Y., The Industrial Press; Lond., the Machinery Pub. Co., Ltd., 1921. 122 pp., illus., 9 x 6 in., paper. $1.00.

For many years broaching has been used for cutting keyways and machining holes to a variety of shapes, but the method attracted little attention until comparatively recently. With the rise of the automobile industry broaching machines came into common use and now are extensively used in building many products. This book is a concise review of modern practise explaining the machines, the design of broaches and the application of the process to many classes of work.

Design and Construction of Power Workboats

By Arthur F. Johnson. Cleveland Penton Pub. Co., 1920. 113 pp., diagrams, tables, 12 x 9 in., cloth. $5.00.

The vessels considered in this volume are those propelled by internal combustion engines and intended for traversing coastwise, harbor or inland waters, embracing ferryboats for freight and passenger service, tugs, lighters, tank boats, trawlers, shop, pumping and wrecking boats. The information is given in detail and illustrated with working drawings.

Electrical Rates

By G. P. Watkins. N. Y., D. Van Nostrand Co., 1921. 228 pp., diagrams, 9 x 6 in., cloth. $3.00.

This book on ratemaking, the outgrowth of nine years experience in the statistical bureau of a public service commission is written from the viewpoint of an economist. The author has endeavored to offer a more extensive explanation and constructive application of economic principles than is customary in works on this subject and to go further into fundamental economic problems. Much space is given to the differential rate theory, to load factors and to density factors.

Electricity in Steel Works

By Wm. McFarlane. London and N. Y., Sir Isaac Pitman & Sons, Ltd., 1921. (Pitman's technical primers.) 109 pp., illus., 6 x 4 in., boards. $1.00.

This review of electrical practise in iron and steel works is intended for students of the steel industry and electrical engineers interested in the special conditions and requirements in steel mills. It attempts to deal with fundamental principles and practise in the generation of electricity for use in steel works, in the use of electric motors for driving rolling mills and in the use of electromagnets and electric lighting.

Heating Systems

By F. W. Raynes. Second edition. Lond. and N. Y., Longmans, Green and Co., 1921. 324 pp., plates, diagrs., tables, 9 x 6 in., cloth. $7.50.

This text book on the design of heating systems presents modern English practise. A special feature is the large number of charts that have been prepared and the method adopted for calculating pipe sizes. The practical rather than the theoretical aspects of the work have been given attention. Consideration is also given to the economical aspect of heating problems, especially in the heating of industrial buildings and plants. The new edition has been brought up to date.

Longwall Coal Cutting Machinery

By G. F. F. Eagar. London and N. Y., Sir Isaac Pitman & Sons, Ltd., 1921. (Pitman's technical primers.) 109 pp., illus., 6 x 4 in., boards. $1.00.

This primer is a concise review of the whole subject, with especial reference to practical aspects, and is intended to assist in the correct application of coal cutting machinery and the selection of the proper type of machine for given conditions.

Manhood of Humanity

By Alfred Korzybski. N. Y., E. P. Dutton & Co., 1921. 264 pp., 8 x 6 in., cloth. $3.00.

This book is primarily a study of man and ultimately embraces all the great qualities and problems of man. The author approaches the problem from a mathematical, an engineering

point of view, with the object of ascertaining what man's real nature is and what the basic laws of his nature are, and hopes thus to point the way to a science of directing human energies and capacities to the advancement of human welfare.

THE MECHANICAL PRODUCTION OF GOLD

By Sir J. A. Ewing. Second edition. Cambridge, University Press, 1921. 204 pp., diagrs., 9 x 6 in., cloth. $8.00. (Gift of the MacMillan Co., N. Y.)

This book contains the "Howard" Lectures delivered before the Society of Arts in 1897, as revised and reprinted in 1908. It provides a general account of refrigeration, in which stress is laid on the thermodynamic aspect of the subject, and an attempt is made to render this aspect intelligible without unnecessary mathematics. The changes in this edition are the correction of certain errata and the clearing up of some obscure points.

THE ORIFICE METER AND GAS MEASUREMENT

By Willis C. Brown and Malcolm B. Hall, Foxboro, Mass., The Foxboro Co., Inc., 1921. 112 pp., tables, illus., 8 x 5 in., cloth. $3.50.

This book, published by the manufacturers of the first commercial orifice meter, gives authentic information on orifice coefficients and their derivation, together with complete details of the mechanical construction of their own meter.

POWER FACTOR CORRECTION

By A. E. Clayton. London and N. Y., Sir Isaac Pitman & Sons, Ltd., 1921. (Pitman's technical primers.) 108 pp., illus., 6 x 4 in., boards. $1.00.

This little book presents the fundamental principles of power factor correction in an easily digestible form, without attempting a complete treatment of the subject. It discusses the use of static and rotary condensers and of phase advancers for improving the power factor, concentrating attention upon the principles governing their action, without attempting to describe every proposed device.

TESTING OF CONTINUOUS CURRENT MACHINES

By Charles F. Smith. London and N. Y., Sir Isaac Pitman & Sons, Ltd., 1921. (Pitman's technical primers.) 102 pp., illus., 6 x 4 in., boards. $1.00.

This book attempts to give in compact form an outline of the main principles underlying the practise of testing electrical machines for commercial purposes. Simplicity and emphasis on the main purposes of the tests have been the chief aim, so that much detail and many tests of limited application have been excluded. The book is intended for young engineers.

WIRING FOR LIGHT AND POWER

By Terrell Croft. Ed. 3 N. Y. and Lond., McGraw-Hill Book Co., Inc., 1921. Illus., 7½ x 5 in., cloth. $3.00.

This book is designed to fill the need for a wiring handbook that meets the requirements of the National Electrical Code, and at the same time describes and illustrates the best American practise in wiring. This edition includes a supplement covering the changes introduced in the 1920 issue of the National Electrical Code.

THE CODE AT A GLANCE

Hubert S. Wynkoop, M. E.

"The Code at a Glance" is a pocket size book with durable binding, prepared by Hubert S. Wynkoop M. E. Wherever any sort of an electrical inspection service exists—whether state, municipal or underwriters—the installation of electric wiring and appliances for light, heat or power, and quite frequently for signalling, must be performed in the manner specified in the National Electrical Code.

For twenty-five years Mr. Wynkoop has been at the head of the electrical inspection service of the City of New York, and no one appreciates better than he the need for a concise and easily consulted transcript of the Code. Consequently he has rearranged in alphabetical order all the Code requirements which it is essential for the contractor, the wireman, the estimator, and the inspector to have constantly in mind. The book is published by National Association of Electrical Contractors and Dealers, 15 West 37th Street, New York.

SECTION AND BRANCH MEETINGS

PAST SECTION MEETINGS

Portland.—June 30, 1921, University Club. Informal talk by President Berresford on the activities of the A. I. E. E., the welfare work being done and the recommendations made at the Section delegates' meeting at the Salt Lake City Convention. Attendance 25.

San Francisco.—July 6, 1921, Engineers Club. Informal dinner with President Berresford as the guest. Following the dinner President Berresford gave a very interesting talk on the status of the engineer and outlined the obligations which engineers owe the profession, and the advantages to be gained by association in an engineering society. Attendance 50.

Spokane.—June 27, 1921, Davenport Hotel. Dinner in honor of President Berresford, and a talk by him on Institute affairs in general. Attendance 20.

Vancouver.—June 3rd, 1921. Election of officers as follows: Chairman, John R. Read; Secretary, W. F. McNeill; Executive Committee, Messrs. Frannk Sawford, L. P. Philpot and T. H. Crosby. Attendance 20.

June 29, 1921, Terminal City Club. Informal dinner, followed by an open meeting at which President Berresford discussed matters of interest to the Section and the Institute as a whole. Attendance 35.

PAST BRANCH MEETING

University of California.—August 24, 1921. Election of Vice-Chairman and discussion of future program. Attendance 14.

ADDRESSES WANTED

A list of members whose mail has been returned by the Postal Authorities, is given below, together with the address as they now appear on the Institute records. Any member knowing the present address of any of these members is requested to communicate with the Secretary at 33 West 39th Street.

1.—Roy L. Ehmann, 4636 North St. Louis Ave., Chicago, Ill.
2.—Wm. J. Epps, Rua Dom Geraldo 80, Rio de Janeiro, Brazil, S. A.
3.—G. Foung, Kay Sang & Co., 843 Clay St., San Francisco, Calif.
4. W. F. Gantvoort, Kedongsarie 84, Soerabaia, Java, Dutch East Indies.
5.—T. J. Hodge, 612 West 137th St., New York, N. Y.
6.—Conrad Jacobson, Hood River, Ore.
7.—G. H. Lindsey, Rosemere Apts., 2255 West 14th St., Los Angeles, Calif.
8.—Geo. C. McCabe, 137 West 86th St., New York, N. Y.
9.—Harry P. Meyer, 327 East 61st Street, Los Angeles, Calif.
10.—Chas. Schindler, Great Western Power Co., Crockett, Calif.
11.—E. V. Stoute, 1946 Mosher St., Baltimore, Md.
12.—Frank N. Tucker, 551 East 40th Street, Chicago, Ill.

EMPLOYMENT SERVICE BULLETIN

OPPORTUNITIES.—Desirable opportunities for service from responsible sources are announced in this Bulletin, and no charge therefor is made.

MEN AVAILABLE.—Under this heading brief announcements (not more than fifty words) will be published without charge to the members. Announcements will not be repeated except upon request received after a period of three months, during which period names and records will remain in the active files.

NOTE.—Notices for the JOURNAL **should be addressed to EMPLOYMENT SERVICE, 33 West 39th Street, New York, N. Y.,** *the employment clearing house of the Societies constituting the Federated American Engineering Societies, and* **not** *to the A. I. E. E.*

Notices for the JOURNAL are not acknowledged by personal letter, but is received prior to the 16th of the month will appear in the issue of the following month.

All replies to either "Opportunities" or "Services Available" should be addressed to the key number indicated in each case **and forwarded to EMPLOYMENT SERVICE, as above.**

Replies received by the bureau after the position to which they refer has been filed will not be forwarded, and will be held by the bureau for one month only.

Information regarding the notices published is on file in the offices of the member societies of the Federated American Engineering Societies.

POSITIONS OPEN

RESEARCH ASSISTANT familar with theory of transmission lines and a-c. machinery. Must be good in mathematics and a fair mechanical designer. Will be allowed to attend a few classes in Cornell University. Location N. Y. X-894.

SALES ENGINEER experienced in belting. Must have sales experience and speak Spanish fluently. Application by letter only. X-907.

ENGINEER having ability as a correspondent, also with a full technical and practical knowledge of pumps and electric machinery as well as the application thereof, together with a personality which will qualify him for direct sales work. Application by letter only. Location Chicago. X-929.

LUBRICATING ENGINEER. Must be a graduate M. E. and able to speak Spanish fluently. Unmarried man desired on account of housing conditions. Location Philippine Islands. X-975.

HYDROELECTRIC SWITCHBOARD OPERATOR for Chile. Salary $200 per month, $50 for board. Two year contract, includes traveling expenses. If married, 3 years contract includes traveling expenses for wife. X-976.

CHIEF ELECTRICIAN for construction maintenance and repairs for mining company in Chile. Salary $300 per month, board $50 per month. Two years contract, all traveling expenses. If married a 3 years contract and wife's traveling expenses. X-977.

MECHANICAL ENGINEER well known amongst engineers, architects and contractors of New York City and vicinity to sell insulation material for manufacturing company well known in its field and well established. X-989.

SUPERINTENDENT. Age about 35. Must be experienced in rubber industry and such operations as milling, calendering and curing of rubber. Must be able to handle men to get along with them. Must be capable of taking entire charge of plant and its operations. Should be technician and be acquainted with modern practises in planning and scheduling work. X-991.

SALES ENGINEERS, preferably with some sales experience who are willing to work at the present time on straight commission basis selling motors, generators, fans, blowers, and commutator slotters and stones. Location New York City. X-1013.

WANTED: Consulting engineers experienced in building design are wanted as sales representatives in the following cities: Dayton, Columbus, Cincinnati, San Francisco, Los Angeles, Spokane, Seattle, Takoma, Toledo, Buffalo, Rochester, Atlanta, Denver, Salt Lake City, Montreal and Toronto. The work does not require a large amount of time but men of the very best calibre are absolutely essential. The sales representative must be a man who is in close touch with the building situation in his territory. Sales experience is not as important as ability to think straight. Each territory offers a splendid opportunity for the right man. X-1015.

RECENT ELECTRICAL ENGINEERING GRADUATE with two or three years sales experience for sales department of motor manufacturer. Give age, experience, and general qualifications for this work. X-1029.

ELECTRICAL ENGINEER with condenser and amplifier experience for research work on Phonodik. The condenser experience is essential. Three afternoons per week. Location New York City. X-1046.

ELECTRICAL DESIGNER who has had past experience in the design of small intricate electrical apparatus of a precision character. Location New York. X-1059.

MECHANICAL OR INDUSTRIAL ENGINEER, able to take financial interest in small but profitable manufacturing business. Able to take complete charge, relieving owners from details of management. Location, New York and Philadelphia. X-1065.

ASSISTANT SUPERINTENDENT of Power and Shops, capable of handling the work as the Supt. in his abscence, as a director of hydroelectric and steam power plants, factory electrical maintenance, machine shops, belt shop, tin shop, blacksmith shop, etc., also drafting room, employing altogether about 200 men. Position open in December. X-1076.

MEN AVAILABLE

ELECTRICAL ENGINEER, age 25, with three years experience in business and engineering including General Electric test, wishes position as assistant to active consulting engineer. Character and education the best. Available on moderate notice. West preferred. E-2968.

INDUCTION MOTOR ENGINEER. High grade electrical-mechanical engineer, age 36, with 14 years factory experience seeks opening with motor manufacturer. Knows every phase of motor game from first design to final application. Engineering records and factory processes a specialty. Salary secondary. E-2969.

ELECTRICAL ENGINEER desires opportunity to do original research work in the field of communication. Technical graduate. Has done experimental and development work in commercial electrical laboratory, also at five high-power radio stations. E-2970.

CONSTRUCTION AND MAINTENANCE ENGINEER, age 28 married. Eight years electro-mechanical construction and maintenance in large manufacturing concern. Three years superintendent of engineering on electrical, mechanical, refrigeration, steam and laboratory with same concern. Has knowledge of food chemistry. Can handle men. Can purchase and supervise stocking of all supplies. Available on short notice. E-2971.

EXECUTIVE-ELECTRICAL ENGINEER, age 36; 14 years experience in various phases of engineering and manufacturing. Would like executive position where there is an opportunity for advancement. Can handle people and get results. Present salary $4500. Good reasons for changing and can furnish references from past employers. Immediate salary not of great importance if position has future. E-2972.

EXPERIENCED ELECTRICAL ENGINEER: Technical graduate with nine years power and lighting experience in manufacturing and construction works desires executive position with engineering firm. E-2973.

SALES ENGINEER. Two years sales, six years broad electrical and mechanical engineering experience. Aggressive and resourceful. Graduate electrical engineer. Associate A. I. E. E. Age 30. Highest recommendations. E-2974.

GRADUATE ELECTRICAL ENGINEER. Age 23, single, desires connection with electric railway or power transmission construction company doing work in foreign country. South America or Asia preferred. Over one year experience G. E. test. E-2975.

ELECTRICAL DRAUGHTSMAN with 10 years experience as line foreman and telephone switchboard man; 4 years engineering experience in the design and layout of radio equipment and telephone apparatus and systems. Available at once. E-2976.

ARC WELDING machinery development position desired by technical graduate, University of Wisconsin 1918. Experience in research and development of automatic arc welding machinery; in design and manufacture of industrial motors a-c. and d-c.; and as engineer officer in U. S. Navy. Married. Salary $2600. Available Nov. 1. E-2977.

ELECTRICAL ENGINEER, Assoc. A. I. E. E., B. S. degree; unmarried; age 24; one year G. E. test; 2½ years sales engineering; desires position with reliable concern preferably in Middle West, but will go anywhere. Able to produce results in commercial engineering. Available immediately. E-2978.

ELECTRICAL ENGINEER, 1914 graduate, desires connection with consulting engineer handling public utility cases, or sales engineering position where engineering ability is of primary importance. Principal experience; one year electrical testing; 2½ years in engineering dept. of a public service commission; 3½ years in eng'g. dept. of a large oil refinery. Age 28. Married. Present salary $3000. E-2979.

ELECTRICAL ENGINEER age 28. Assoc. A. I. E. E., Jou. Mem. A. S. M. E. Chief Elec-

trician, U. S. N. 9 years service. General foreman of construction and assistant engineer in charge of construction. 10 years practical experience, 5 years d. c. and 5 years a. c. Wishes position with chance of advancement. Location anywhere. E-2980.

CHIEF ELECTRICIAN, Industrial plant, age 36, married. 16 years experience installation, operating and maintenance, d-c. and a-c. equipment. 12 years with present connection, past 9 years chief electrician. Will consider any position where chance for advancement. Location preferred east of Pittsburgh, Pa. E-2981.

RECENT GRADUATE ELECTRICAL ENGINEER, University of Michigan. Age 27. Two years practical experience with steam railroad. Position wanted with some well established electrical concern. Location U. S. Available immediately. E-2982.

JUNIOR ENGINEER OR DESIGNER. 100 per cent American, honest and trustworthy. Technical graduate (B. Sc. degree), age 24. Has had experience as electrical and mechanical draftsman and designer. Practical machine shop experience. Familiar with experimental and production developments. Expert mathematician. E-2983.

ELECTRICAL ENGINEER, technical graduate, Associate A. I. E. E. Fifteen years practical experience in quantity manufacture of small electrical and mechanical devices; electrical measuring apparatus a specialty. Designing or or developmental engineering preferred. Fully qualified for supervision of manufacturing plant of moderate capacity. Available on short notice. E-2984.

GRADUATE ELECTRICAL ENGINEER. Age 26, desires position. Has had two years design and manufacturing experience but is anxious to secure position as assistant production manager where engineering and manufacturing experience are assets. E-2985.

SALES MANAGER at present occupying this position with satisfaction to employer will consider a change. Broad experience in electrical engineering, and allied lines. Excellent sales training and record, only position of responsibility considered. E-2986.

ELECTRICAL ENGINEERING STUDENT, 5th year Cooper Union Night; age 20 years, single, three years experience in telephone maintenance, etc. Desires to hear from concerns which offer advancement and a future. Locality, New York City. E-2987.

ELECTRICAL ENGINEER, Graduate of University of Nebraska, 1916. Age 28; married. Experience: 2 years G. E. test; 18 months high-voltage underground cable and dielectric investigations; 18 months industrial application engineer, specializing on electricity in the sugar and rubber industries; also acquainted with design, appraisal and electrical contracting. Salary depends on location. Associate A. I. E. E. Available on short notice if necessary. E-2988.

ELECTRICAL ENGINEER, available for either U. S. A. or foreign service. Desirous to connect with concern with a future. Teaching experience two years, manager and foreman in electrical contracting business for the past three years. Expert on generators and motor. Assoc. A. I. E. E., age 27. E-2989.

ELECTRICAL MECHANICAL RESEARCH ENGINEER; B. S. degree; age 28; married, with six years experience in development and invention work desires position, preferably in Eastern States. Salary is not as important as opportunity to advance when ability is demonstrated. An opportunity to acquire detailed experience in electrical design is especially desired. E-2990.

ELECTRICAL AND CRANE SALES ENGINEER, 40 years old, desires position with reliable concern to develop and market any materials-handling apparatus or to sell for established concern. Have a broad active record and ambition to get ahead. Member A. I. E. E., Sigma Xi, E. K. N. Fuller information by appointment or letter. E-2991.

ELECTRICAL ENGINEER, graduate of Purdue University, married. Member Tau Beta Pi, Associate A. I. E. E. Seven years practical experience in sales, production, costs and engineering work. Would consider either practical or educational work. E-2992.

MANAGER OR SUPERINTENDENT of railway, gas, electric lighting and power properties; long experience in economical management, construction and maintenance, good on rehabilitating run-down properties; university education, married; desires a position where initiative, hard work and results would be recognized. E-2993.

SALES ENGINEER, technical graduate. Completed instruction course with Cutler-Hammer Mfg. Co. Successful sales experience in district office. Wish to represent a well known concern on a salary and commission basis. E-2994.

MANAGER, Electrical Engineer, thoroughly experienced in public utility management and operation of steam and hydroelectric plants and railways. Versed in technical and engineering details, and in office management. Tactful and successful in dealing with public. Available at once. E-2995.

ELECTRICIAN, married, 26. Californian, returning to Oakland, available January 1, 1922. Practical eight years' experience including navy, factory test of industrial heating and controlling appliances, maintenance of axle lighting and storage battery equipment. Capable of handling men. Prefer position in charge of factory, power plant, in vicinity of San Francisco Bay cities. Best of references. E-2996.

ENGINEER, sixteen years experience in design and manufacture of direct and alternating-current motors to one hundred horse power. Have developed number special motors for application to various classes apparatus. Appreciate value of simplicity of mechanical design in relation manufacturing costs. Considerable executive and sales experience. E-2997.

ELECTRICAL ENGINEER, technical graduate, age 30 years. Assoc. A. I. E. E. Four years experience in testing, construction and maintenance. Location, east of Mississippi River. Available immediately. E-2998.

CHEMICAL ENGINEER, 1917, four years experience in electrical laboratory of large brass company, on a most varied line of work, ranging from the setting up of production tests of small motors to the development of intricate and novel relays. A position of responsibility is desired, preferably in Philadelphia or vicinity. E-2999.

CONSTRUCTION SUPERINTENDENT OR ASSISTANT ENGINEER, on power house or transmission line construction or operation. Sixteen years experience in electrical work, including five years as chief operator of power company. Desires to get in touch with engineering companies engaged in development work in Central and South America, chiefly along hydroelectric lines. E-3000.

ELECTRICAL ENGINEER, technical graduate, with broad business, sales and executive experience, desires situation with central station, consulting or contracting engineer, or with manufacturer or export company. Six years in Mexico, five years with Westinghouse company in engineering dept. Age forty. E-3001.

ELECTRICAL AND MECHANICAL ENGINEER, graduate, 5 years experience including G. E. electrical and turbine test; Electrical Expert Aide U. S. Navy Dept., Experimental and test engineer for turbine manufacturer; at present making special power studies; desires position with manufacturing concern or as maintenance engineer or with power company. Will also consider foreign service. Married, 29 years of age. E-3002.

EXECUTIVE with the management viewpoint. 14 years experience in construction operation and management of public utility properties. Trained in engineering and higher accounting. Has filled positions as resident engineer, superintendent, controller and general manager. At present with large engineering concern. Age 34. Salary six thousand. E-3003.

ELECTRICAL ENGINEER, age 26, college graduate, (U. S. A.) with one year of post graduate work in Sweden, desires position, preferably with hydroelectric company, but will consider any position with opportunity for advancement. Experience includes some high-voltage test work, installation of small apparatus and general wiring. E-3004.

POWER PLANT ENGINEER, age 34, competent trustworthy, technical training. Experience, steam and hydroelectric operation and maintenance covering eight years. Six years' experience as chief electrician. Desires position with company offering permanent employment with future opporunity for advancement. Location, Michigan or nearby preferred. Assoc. A. I. E. E. Available immediately. E-3005.

ELECTRICAL ENGINEER, Technical Graduate, age 25. With executive and business ability, desires to connect with small utilities company. Capable of managing same. Three years experience on transmission, distribution, operation and power contracting, one year on G. E. test. Six months power plant experience. Single, energetic. Location immaterial, available in two weeks. E-3006.

ELECTRICAL ENGINEER, Missouri University 1912, electrical testing two years, general engineering, including sales engineering (manufacturing and public utilities) three years. Transformer and a-c. motor designing four years. Also teaching experience in mathematics and electricity. Location St. Louis or vicinity. Salary $3000. E-3007.

STEAM-ELECTRIC PLANT ENGINEER. Technical graduate, seven years with General Electric Co. in test, laboratory, design, developmental and commercial work. Three years steam plant testing and engineering. Familiar with oil burning boiler room practise and various metering devices of a modern steam turbine plant. Prefer power plant work. E-3008.

ELECTRICAL ENGINEER, age 31 years, married, desires position on railroad, electrification project, or as works engineer in industrial concern. Previous experience; electrical testing, public-utility appraisal and construction-inspection, army officer, drafting and designing in rubber manufacturing plant. Location preferred, Chicago or mountain West. Two weeks notice. E-3009.

FACTORY EXECUTIVE, age 35. Electrical and Mechanical Engineer 15 years' experience in the operation of industrial power plants and in factory management. Last 5 years, production manager in large factories manufacturing electrical machinery and automobile engines. Available Oct. 1. Location immaterial. Opportunity not salary is prime consideration. E-3010.

ELECTRICAL ENGINEER, B. S. degree Age 23, single. Desires position with power or manufacturing concern, also had four years experience at the tool and die making line. Location in the East preferred. Available at once. E-3011.

APPLICATIONS FOR ELECTION

Applications have been received by the Secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a higher grade than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the Secretary before October 31, 1921.

Barnes, Lynn G., Schenectady, N. Y.
Barrett, Arthur C., Las Cruces, New Mexico.
Barron, Frederick H., Amsterdam, N. Y.
Baskin, John P., Atlanta, Ga.
D'Andrea, Michael E., Rockville Centre, N. Y.
Dohl, Alfred P., E. St. Louis, Ill.
Eckles, Fayette B., Kansas City, Mo.
Elznic, Felix F., New York, N. Y.
Emmons, Norman E., (Member), Hartford, Conn.
Fossatti, P. G., Jay, Maine.
Gibbon, Thomas H., Toronto, Ont.
Glass, Paul W., New York, N. Y.
Grabe, Clarence G., (Member), Pittsburgh, Pa.
Harty, Edgar A., New York, N. Y.
Holladay, Collis H., Los Angeles, Cal.
Hoxie, Harvey H., San Francisco, Cal.
Hoyle, Bernard C., Lynn, Mass.
Johnson, Martin A., St. Joseph, Mo.
Klapholz, Maurice, Harrison, N. J.
Matz, Charles, Hammond, Ind.
McGinty, Ernest A., San Francisco, Cal.
McMann, Renville H., New York, N. Y.
Newcomb, Harry F., Pittsburgh, Pa.
Pestel, Arthur, New York, N. Y.
Rathgeb, Charles C., Three Rivers, Que.
Scribner, Elmer B., New York, N. Y.
Sery, Ralph J., Monroe, Wisconsin
Shea, Thomas F., Pittsburgh, Pa.

Vol. XL NOVEMBER, 1921 Number 11

Electric Propulsion of Ships

BY W. E. THAU

Marine Department, Westinghouse Electric and Manufacturing Co.

THIS paper deals primarily with the electric propulsion of ships, except wherein a comparison of some particular feature or characteristic warrants a reference to some other type of drive. In dealing with electric propulsion, it is necessary to consider all classes of ships, and this leads to two broad, general classifications, such as merchant ships and war vessels.

Merchant Ship Propulsive Equipment

General Requirements

The ultimate purpose of a merchant ship is to earn money. From this standpoint, the factors of reliability, economy, weight, space, cost, operation and maintenance are involved in the propulsive equipment. Therefore the type of drive most suitable is that which excels in all or the most important of these factors. The relative importance of these items varies with different ships, depending upon the trade route, cargo, etc., with the result that there is a definite and logical field for each of the principal types of drives, such as reciprocating engine, geared turbine, turbine-electric, Diesel and Diesel-electric. Since many general comparisons of the principal types of drives in regard to these factors have been given in recent articles in the technical press it is not the intent of the present paper to take up this phase of the subject, but rather to analyze the principal types of electric propulsive equipments and to show in general how they fulfill these requirements.

Reliability

The universal use of, and the indisputable success of electrical apparatus on land is sufficient testimony in behalf of its reliability. The absence of reciprocating parts makes electrical apparatus with its simple rotation as reliable as can be desired. It can almost be said that there are no mechanical troubles with electrical machinery. Broadly speaking, there are no new principles involved in the application of electrical apparatus to ship propulsion. It is true that ship conditions differ from land conditions in certain respects, but there is no phase of the application which presents any really serious difficulty. The most important adverse condition is the deleterious effect of salt and moisture, which is easily surmounted by proper insulation of the windings and circuits, as is obvious from the several years of successful operation of present electric propulsion equipments. There can, therefore, be no question as to the reliability of electrical propulsive equipment.

Economy

Economy is an important factor, and must be given due consideration. To properly analyze this item, it is necessary to consider all equipment involved in the propulsion, with respect to fuel, water, lubricants and supplies. The relative proportions of these items vary considerably in the different types of propulsive equipments. The turbine-electric and the geared turbine compare very closely in economy when all items are considered. The losses in the reversing elements of geared turbines, the losses in the gears and the power required to circulate the additional lubricating oil, detract appreciably from the gain which the geared turbine would otherwise have over the turbine-electric because of the inherent electrical losses in the latter. Generally speaking, the net economy of a properly designed and constructed geared turbine drive should be better than a turbine-electric drive, even though full advantage is taken of every practical source of gain in the latter. The difference, however, is perhaps hardly of sufficient magnitude to be the dominating factor in arriving at a final selection. The economy of a reciprocating engine drive is obviously poorer than that of a properly designed turbine drive of either type for the reason that the reciprocating engine cannot utilize the same expansion of the steam.

It has been advanced that the turbine for the turbine-electric system, being a one-direction rotation machine, can utilize higher superheat than the geared turbine, because of the reversing element of the latter, thus resulting in better overall economy. With the present installations, this condition is true to some extent. However, with proper attention given to this factor, geared turbines can be designed to operate without detriment with steam superheated 150 to 200 deg.

To be presented at the Joint Meeting of the A. I. E. E. and the Society of Naval Architects and Marine Engineers, New York, N. Y., November 17, 1921. Printed in advance to facilitate discussion.

fahr., which is fairly close to the practical limit of superheat on board ship, as there are other items aside from the turbines which are affected by high superheats to the extent of fixing limitations.

Obviously from a fuel consumption standpoint, the direct Diesel and Diesel-electric propulsive equipments offer by far the best economy. Of these two types, it would appear, offhand, that the direct Diesel drive is decidedly superior to the Diesel-electric; however, it will be shown later that there are certain limitations in the direct Diesel drive which offset its advantage in fuel per brake horse-power-hour over the Diesel-electric. Here again, it is obvious that all items related to the propulsive equipment must be taken into consideration to obtain the ultimate answer.

Weight

The item of weight would probably show more variance than other items owing to differences of arrangement, design, foundations, etc., in the practise of the several ship builders. The importance of weight depends upon the type of ship, cargo, and trade route. Usually, however, weight is an important item as it has a direct effect upon the total fuel consumption and the amount of cargo that can be carried with a given displacement. Here again, it is necessary to consider all items related to the propulsive equipment. A correct comparison of weight necessitates that the equipments under consideration be on the same basis relative to overload, factor of safety and arrangement. This is particularly important in comparisons between electric drive equipments. Where one equipment affords an advantage in flexibility of reserve, however, it is usually at some sacrifice in weight, and an allowance must be made.

Space

Space is important in that it has a direct bearing upon the bulk of cargo that can be carried. Its relative importance depends somewhat upon the location of the machinery, *i. e.*, whether the machinery is located amidship or aft, or both. Space is affected by the distribution of machinery and the relative saving depends somewhat upon the practise of the various ship builders in that respect. General analysis of the space factors which have been made thus far gives the advantage to the direct-connected Diesel and Diesel-electric types of propulsive equipment, the saving being effected by the elimination of the boilers and reduction of fuel and water tanks. Of the turbine-electric and geared turbine types, the space factor is in favor of the geared turbine, except in special cases. The general arrangement of the engine room, number of propellers and the beam of the ship have a direct effect upon the space occupied as a result of machinery distribution. By locating the condensers underneath the turbines in electric drives, the total floor space can be greatly reduced.

Cost

A definite comparison of costs is still a difficult task owing to the continued unsettled conditions. On the basis of equal performance in regard to propeller torque and speed, the cost including all items related to the propulsive equipment should run in the order of direct-Diesel, turbine-electric, geared turbine, and Diesel-electric, the latter being the cheapest. The paradox in the relative cost of direct-Diesel and Diesel-electric is explained by the condition that small Diesel engines and generators for Diesel-electric drives can be manufactured ultimately on a large production basis and stocked, whereas the engines for direct-Diesel drive, and to a large extent, the two types of turbine drive, because of their large size and weight, must almost of necessity be a building proposition. On the basis of standardized drives, there should not be a great deal in favor of the geared turbine as compared with the turbine-electric drive. This comparison will vary somewhat with the different manufacturers.

The initial cost of the propulsive equipment has a direct effect upon the net earning power of the ship, because of interest, depreciation and insurance charges, and therefore, cost is an important item.

Operation

In regard to operation, it is realized that the present operators are largely men who are more familiar with reciprocating engines than with other types of machinery, and that for this reason, certain difficulties are likely to be encountered in placing electrical equipments in their hands. The author believes that this thought should not be a consideration, as it is a temporary condition only. The horse car driver became the motorman of the electric car, the reciprocating plant operator became the turbine plant operator in the central station, the steam locomotive engineer became the electric locomotive engineer (engineers now operating electric locomotives are reluctant to return to the steam locomotive), and similarly countless examples may be mentioned to show that change in machinery represents no obstacle. Successful operators of electrical machinery need not have sufficient knowledge of it to understand the details of its design. This is not the case on land and there is no greater reason for it on the sea. The operator should, however, know the operating characteristics of electrical apparatus and how to take care of it.

The same question was raised in the case of geared turbines only a few years ago, yet today there is nearly a sufficient number of competent geared turbine operators to take care of all the geared turbine ships. The same will be the case with operators for electric ships. It is merely a matter of training and education and it is certainly a reflection upon the intelligence of the age to classify the present limited knowledge as an obstacle for consideration.

The following is a probable list of the operating

personnel for the principal types of drives. The cost of operating personnel as based upon this list would, therefore, be in the order of,—direct-connected Diesel, turbine-electric, geared turbine, reciprocating engine, and Diesel-electric:

TABLE OF PROBABLE OPERATING PERSONNEL.

		Reciprocating engine	Geared turbine	Turbine electric	Direct connected diesel	Diesel electric
		*	*	*		
Total Crew	Chief	1	1	1	1	1
	1st. Asst	1	1	1	1	
	2nd. Asst	1	1	1	1	1
	3rd. Asst	1	1	1	1	1
	Jr. Engrs	0	0	0	3	0
	Electricians	0	0	1	1	1
	Oilers	3	3	3	6	6
	Firemen	6	6	6	0	0
	Total	13	13	14	14	1[illegible]
On each watch	1st., 2d or 3d	1	1	1	1	1
	Junior Engrs	0	0	0	1	0
	Electricians	0	0	0	0	0
	Oilers	1	1	1	2	2
	Firemen	2	2	2	0	0
	Total	4	4	4	4	3

*Based on oil burning ships. For coal ships, the operating personnel would be augmented by three coal passers.

Maintenance

Although there are practically no data available on the maintenance of electrical propulsive equipments (except battleships), there is no reason to anticipate any great difference between sea and land practise. As a matter of fact, there is reason to anticipate less maintenance for the reason that the load conditions and control operations are less severe than is the case with most land installations involving large machinery. If the equipment is given proper care and inspection, the maintenance item will be low, as the absence of rubbing parts (except for the bearings), leaves little to get out of order. Electrical machinery does not wear as is the case with other machinery. Furthermore, all probable repairs are such as can be made aboard the ship without the use of an elaborate machine shop.

Performance Characteristics

The inherent performance characteristics of electrical machines are particularly well suited to ship propulsion. Having identical operating characteristics in either direction of rotation, all types of electric drive inherently afford, or can be made to afford, full torque and power for reversal. For reasons of economy, space and cost, the reversing element of a geared turbine is designed to give only 40 per cent to 60 per cent power in the reverse direction. It has been claimed that full reverse power is not essential to a merchant ship, and this is true under ordinary conditions. In emergency, however, it is desirable to stop the ship very quickly, and in this connection it might be pointed out that the electric ship can be stopped in considerably less time than a geared turbine ship. This is not altogether the result of less backing power, but is due to a great extent to the inefficiency of the reversing element of the geared turbine causing an enormous draft on the boilers which greatly reduces the steam pressure.

In reversing, the energy put into the screws by the action of the water and the stored energy in the rotating parts attached to the propeller shaft, must be dissipated in some manner. In the case of the geared turbine, this energy is consumed in doing work on the steam. In the case of a-c. electric drives, the energy of reversal is dissipated in the motor and generator windings, the rotors of the motors, or in external resistors connected to the rotor circuits, depending upon the type of motor used. In d-c. electric drives, the reversal energy must be absorbed elsewhere in the system. The amount of energy to be dissipated or absorbed in the case of a given ship depends entirely upon the time taken to stop the screws. The instant the screws commence to turn over in the reverse direction, the system must supply the energy and all further stopping energy is dissipated at the propellers. There are two factors to be considered in stopping, namely, the energy returned through the propellers, and the stored energy in the propellers and the motor armatures. Analysis shows that reversing even at full speed is not a serious problem, and that it does not place as severe requirements upon the electrical machinery as does turning with hard-over rudder. The details of the distribution and absorption of the energy of reversal would occupy too much space to be discussed at this time. Suffice it for the present to say that the inherent facilities afforded by electrical systems for dissipating energy and for giving full power in either direction are what make the electric drives ideally suited for stopping. The time required to stop an electric ship is the same as, or less than, that of other drives.

Description of Electrical Propulsive Equipments

General Classification

Electrical systems for ship propulsion may be classified into two general types from the standpoint of the prime movers, namely, turbine-electric and Diesel-electric. Due to the inherent performance of these two types of prime movers, both kinds of electric machinery are used; a-c. machinery with turbine-electric because the a-c. generator is inherently suitable for direct connection to the economical high-speed turbine; and d-c. machinery with Diesel-electric drive because the inherent characteristics of the d-c. generator are ideally suited to Diesel engine performance.

The electrical equipment for turbine-electric drive may be further sub-divided as follows, in regard to the type of motor:

1 Induction
- Wound secondary
  - Ordinary, and with power factor correction
- Squirrel cage
- Combined squirrel cage and wound secondary

2 Synchronous

In the case of the Diesel-electric drive, there is no broad subdivision. As a minor classification, this type of drive might be subdivided with respect to the method of generator operation, *i. e.*, series and parallel. However, series operation is so vastly superior that parallel operation can be disregarded except for the purpose of comparison.

Units Involved

A complete turbine-electric drive involves the following apparatus:

Boiler plant	Motor
Evaporation plant	Oiling system
Condenser plant	Exciter set
Turbine	Control
Generator	

A complete Diesel-electric drive involves the following apparatus:

Diesel engines
Generators
Motors
Small auxiliary air compressors
Air bottles
Exciters
Fuel pumps, (if not attached to engine)
Lubricating pumps, (if not attached to engine)
Control

Turbine-Electric

With turbine-electric drive, the electrical equipment is of the a-c. type, principally for the reason that a-c. turbo generators are inherently better suited for the high economical speeds of turbines. The speed at which the turbine operates is influenced by the propeller speed because of the limitation in the number of poles of the motor. Theoretically, an a-c. motor can be built for any even number of poles, but in practise such factors as power factor, (induction motor), diameter and assembly, fix the limit in the neighborhood of 60 to 72 poles. As the motor speed and numbes of poles fix the generator and turbine speed, there ir consequently an approximately fixed limit to turbine speeds. Incidentally, in the case of practically all merchant ships, this speed is lower than the most economical speed of the turbine. As the propeller is most efficient when designed and operated at low speeds, it is advisable not to exceed 90 to 100 rev. per min. for the ordinary merchant ship.

Assuming a propeller speed of 100 rev. per min., a 60-pole motor and a two-pole generator, the generator and consequently the turbine would operate at 3000 rev. per min. (neglecting the slip in case of the induction motor). This gives a reduction from the turbine to the propeller of 30:1, which is approximately the same irrespective of the type of motor used.

Fig. 1 shows a diagrammatic scheme of connections for an induction motor drive of the wound secondary type. Power is supplied from the turbine-driven generator to the induction motor through one of the reversers. The generator is excited from one of the auxiliary geared turbine d-c. sets. Whether the auxiliary set would supply generator excitation only, or simultaneously furnish ship's auxiliary power, depends principally upon the electrification of engine room auxiliaries, winches, etc.

The turbine is under the control of a governor capable of maintaining constant speed over about 75 per cent of the entire speed range. The governor speed control valve is regulated from the control stand by an oil relay valve or system or rods and levers, depending upon the type of governor used. The propeller speed is adjusted by throttling the turbine as

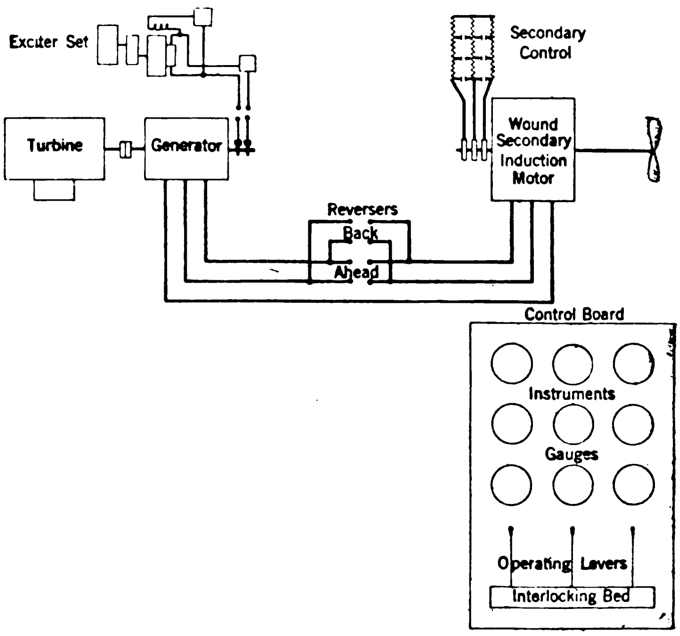

Fig. 1—Wound-Secondary Induction-Motor Drive
Diagrammatic scheme of connections.

in the case of a geared turbine drive. The turbine is started and brought up to its "idling speed" by the throttle valve at the turbine.

Similarly, the generator field switch and rheostat, and the ahead and back switches are controlled from the control stand by means of levers. These levers are mechanically interlocked so that it is necessary to follow the proper sequence of operations in starting, stopping and maneuvering.

Usually, the reversers are interlocked with the field lever so that the field lever must be in the "off" position before the reversers can be opened or closed. Similarly the field is interlocked with the turbine speed control lever so that the control valve must be set for low speed before the field can be opened or closed.

The secondary control is automatic, being either of the solenoid contactor or motor-operated contactor

type. The actuating means is energized through contacts on the field lever near the end of its stroke. This arrangement insures the establishment of voltage at the motor before closing the secondary accelerating switches. Similarly, moving the field lever to the "off" position, opens the secondary switches.

The operating levers and a complete complement of electrical instruments and steam gages are arranged convenient to the operator, the instruments and gages being mounted on a panel directly above or in front of the levers. By observing the instruments, the operator will be kept informed at all times of the performance of all machines, even though the machines be obscured from his view.

By a suitable arrangement of the switches and control levers, the entire maneuvering of a ship of any size and any number of screws, can be under the complete control of one operator.

The interlocking system necessitates the following sequence of operation:

A—Starting Ahead (Turbine Idling):

1. Close Reverser in "Ahead" position,
2. Close Field and establish excitation,
3. Adjust Turbine Speed to desired value after secondary is completely short-circuited. (Indicated by pilot light)

B—Stopping:

1. Move Turbine Speed control lever to idling position,
2. Move Field lever to "off" position.
3. Move Reverser to "off" position.

C—Starting Back:

1. Close Reverser in "Back" position,
2. Close Field and establish excitation,
3. Adjust Turbine Speed to desired value after secondary is completely short-circuited.

D—Reversing (From Ahead Operation):

1. Move Turbine Speed control lever to idling position,
2. Move Field lever to "off" position,
3. Move Reverser from "Ahead" to "Back" position,
4. Move Field lever to full excitation,
5. Bring up Turbine Speed after motor has pulled into step.

The above description applies to a single-screw drive having but one turbine set. For a multiple-screw ship having generating sets for port and starboard sides, the operation would be the same for each side of the ship, as just described.

The above operations are based upon switching when the current in the circuits has been reduced to very low values, or nearly dead circuit conditions. This arrangement is not really necessary, as, with small powers, it is is not essential to open the generator field; however, it may be justified in the light of conservatism. In any event, the reversers are so designed that they are entirely capable of opening full power.

The salient features of the wound-secondary-induction-motor drive are its inherent torque characteristics and the ease of handling. While the secondary control necessitates a few additional switches, this is fully compensated for by the fact that the propeller energy of reversal, and the slip energy of reversal and starting is dissipated in resistors external to the motor. The importance of this is dependent upon the amount of reversing that is done, particularly from full speed. This system, therefore, represents the most conservative arrangement of turbine electric drive.

The squirrel-cage motor system is shown in Fig. 2, and it will be noted that the electrical connections are the same as for the wound-secondary motor system, except that there is no secondary control. This system is, therefore, somewhat simpler than the wound-secondary motor system from an electrical connection standpoint, both inside and outside the motor. It also has a slight advantage in cost in that the motor is less expensive to build. The squirrel-cage motor is shorter because of the absence of collector rings. It has a disadvantage in conservatism and torque characteristics.

The power factor of either of the induction motor systems is less than unity, the exact value depending

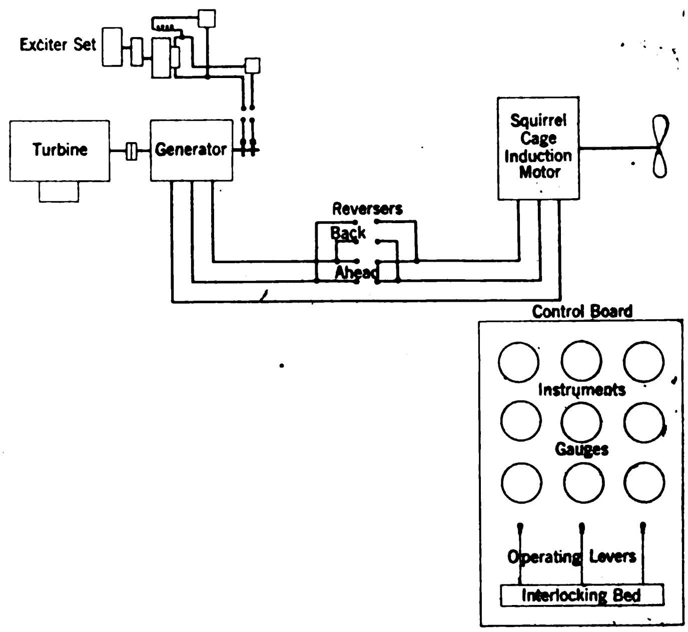

Fig. 2—Squirrel-Cage Induction-Motor Drive
Diagrammatic scheme of connections.

upon the number of poles and certain design features. For the ordinary merchant ship requirements, these motors would have power factors of approximately 70 per cent, the wound-secondary motor having the higher power factor of the two, by a small amount. The induction motor drive, therefore, requires a generator with kv-a. capacity in excess of its kw. capacity, which adds somewhat to its weight and size, and which detracts a very small amount from its efficiency.

The efficiency of the squirrel-cage induction motor of ordinary design is slightly less than that of the wound-secondary motor, for the reason that sufficient permanent resistance must be incorporated in the rotor windings to obtain the required torque for reversal without excessive current. In large motors with special double secondary windings, the required torque can be obtained without excessive current and the

running efficiency can be improved somewhat. Such motors are in use on propeller drives at the present day.

Turbine Electric
(Synchronous)

Fig. 3 shows a diagrammatic scheme of connections for a synchronous motor drive. Power is supplied from the trubine-driven generator to the synchronous motor through one of the reversers. The generator and motor fields are excited from a three-wire, d-c. exciter set. The synchronous motor system differs from the induction motor system only insofar as the synchronous motor itself affects the details of control and generator capacity, the main features of turbine-electric drive being otherwise the same.

Although the characteristics of the ordinary synchronous motors are not suitable for ship propulsion, the synchronous motor can be modified to give characteristics which meet the requirements. The modification consists in providing the rotor with a substantial induction winding of such design and arrangement as will not seriously detract from certain purely synchronous motor characteristics which are desirable.

The maneuvering operations can be accomplished in more than one way. If appreciable torque is required to reverse, the method which appears to be most favorable is to utilize the synchronous characteristics and the induction characteristics at different stages of the reversing cycle. The motor is stopped as a synchronous generator loading into the generator windings which form a dead load (generator field not being excited), then is brought up to nearly synchronous speed in the reverse direction as an induction motor, and finally is pulled into step with the generator as a synchronous motor. With this method, the sequence of operation for reversing would be approximately as follows:

1. Reduce turbine to idling speed (25 per cent.)
2. Open generator and motor fields,
3. Reverse motor connections,
4. Apply motor field excitation bringing motor to rest,
5. De-energize motor field,
6. Energize generator field to double value, bringing motor to nearly synchronous speed as induction motor,
7. Apply normal excitation to motor field, pulling motor into synchronism with generator,
8. Adjust speed to desired value.

The method described above is preferable where appreciable torque is required during reversing. Usually, however, sufficient torque will be developed by the simpler method of reversing as an induction motor, in which case the cycle of operation will be as follows:

1. Reduce turbine to idling speed (25 per cent),
2. Open generator and motor fields,
3. Reverse motor connections,
4. Energize generator field to double value, bringing motor to rest and reversing it to nearly synchronous speed, as an induction motor,
5. Apply normal excitation to motor field, pulling motor into synchronism with generator,
6. Reduce generator field to normal,
7. Adjust speed to desired value.

This method, therefore, simplifies the sequence to the extent of omitting one step and eliminating the generator action of the synchronous motor.

Although eight and seven steps respectively have been indicated in the sequence, some of the steps can be combined so as to reduce the actual number of lever operations to a reasonable amount.

Although the synchronous motor requires special design and introduces additional complications in the control, it has the important inherent characteristic of unity power factor. The unity power factor results in slightly decreased weight and size, and consequently less cost of the motor and generator. Taking the drive as a whole, and considering that both motor and generator must be excited from a separate source at a cost of at least twice the steam per kw-hr. as the main turbine, the efficiency improvement over the induction motor drive is more apparent than real. Therefore, the principal advantages of the synchronous motor drive as compared with the ordinary induction motor drive are a slight saving in cost, weight and space, with a possible inappreciable margin in efficiency.

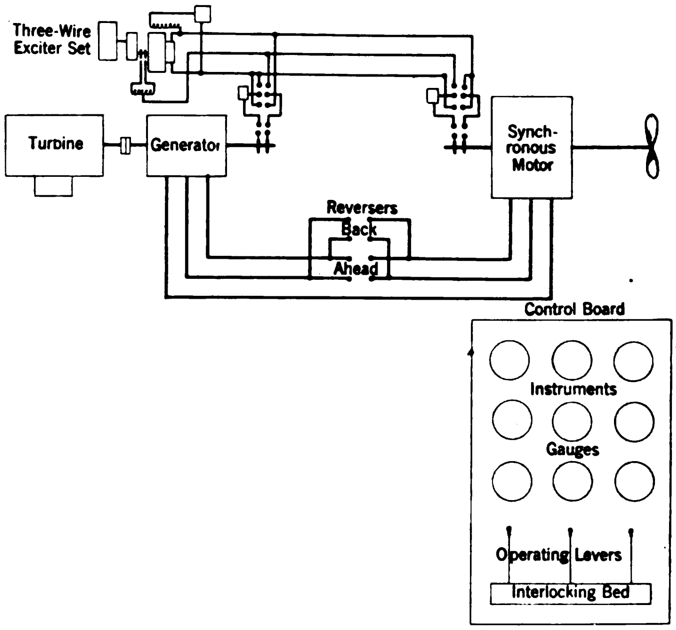

Fig. 3—Synchronous Motor Drive
Diagrammatic scheme of connections.

Turbine Electric
(Induction with Power Factor Correction)

The unity power factor advantage of the synchronous motor system is also available with a wound-secondary induction motor system in which the low lagging power factor is corrected to unity. This arrangement not only provides a system of the same weight, space and cost of the synchronous system, but in addition possesses the superior torque characteristics and simplicity

of control of the wound-secondary induction system.

The diagrammatic scheme of connections is shown in Fig. 4. It will be noted that this is the same as the wound secondary induction motor system shown in Fig. 1, except that power factor corrective apparatus has been added. The scheme functions in the same manner and sequence as that shown in Fig. 1 until the motor is in step with the generator, and at this point the power factor corrective apparatus is caused to function. The corrective apparatus consists of a Le Blanc phase advancer driven by a small d-c. motor, the speed of which may be varied to suit the power factor correction desired. The function of the phase advancer is somewhat similar to that of the d-c. exciter in the case of the synchronous motor in that it supplies excitation to the induction motor. The connection is made to the secondary or rotor winding and thus excitation is supplied through the secondary instead of through the primary, with the result that the primary current is all "power" current, which means "unity" power factor.

The phase advancer is a small commutating machine of very simple construction. The losses in the phase advancer consist of the internal copper loss due to the secondary current, almost negligible iron losses, friction, windage and brush drop. The total of these losses is very little and compares very favorably with the excitation power of the synchronous motor.

The induction motor used with this system is simple in construction, smaller, lighter and consequently less expensive than the motor used with the ordinary wound-secondary induction motor system. The generator is the same as that for the synchronous motor drive. Thus, the induction motor drive with the phase advancer not only provides the advantages resulting from unity power factor, but in addition provides the superior torque characteristics of the wound-secondary induction motor for maneuvering, and also obviates the necessity for synchronous operation with the generator. In fact, it combines all the desirable features and characteristics of both systems, without complications.

Diesel-Electric

For practical reasons, direct current only is feasible with Diesel-electric drive. This will be evident by a proper analysis of the performance of Diesel engines in connection with the characteristics involved in applying a-c. and d-c. machinery, due consideration of ship requirements being taken into account. To obtain the best results with Diesel-electric drive, it is necessary to provide several relatively small and moderately high-speed generating sets for supplying power to single or double-unit direct-connected propelling motors. Not only must the generated power divide evenly or proportionately between the generating units, but the system must also be such as will conveniently and economically lend itself to speed control.

In the case of alternating current, it would be necessary to operate the generators in parallel. To operate a-c. generators in parallel necessitates the very closest speed regulation and practically identical angular velocities of all prime movers. To visualize properly this exacting requirement, it must be remembered that satisfactory parallel operation of a-c. generators necessitates that the angular displacement of the field poles of one machine with respect to another must not vary more than approximately ± 3 electrical degrees, or a total of 6 electrical degrees. Since 360 electrical degrees constitute the space between adjacent like poles, the total variation in mechanical degrees, for example, in the case of a 20-pole machine, must not exceed 0.6 degree. While successful operation under such requirements is carried out in several land installations where the prime movers operate at

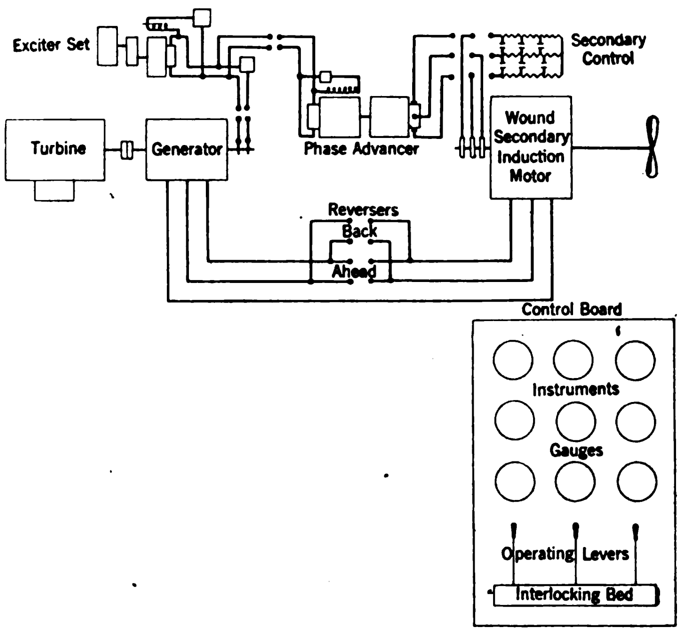

Fig. 4—Wound-Secondary Induction-Motor Drive with Phase Advancer for Power Factor Correction
Diagrammatic scheme of connections.

constant speed, it is not considered safe practise on board ship *where the necessity for varying the speed of all sets simultaneously* introduces another very serious difficulty. To overcome this condition successfully, would require absolutely perfect engine governors which would function 100 per cent perfect at any speed setting. The speed of the motor could be varied by the rheostatic method, thus allowing the engines to operate at constant speed; however, this method is extremely wasteful at reduced speed operation, and at best offers a solution for only one of the many difficulties. It is for these reasons that alternating current is not suitable for Diesel-electric propulsion.

Direct current not only obviates all of the above difficulties, but possesses many advantages in the way of operation, control and reserve power. With direct

current, we have the choice between two methods of generator operation, *i. e.*, parallel and series. From the standpoint of engine performance only, parallel operation of d-c. generators is entirely feasible and easily accomplished. However, when considering economical methods of speed control of the propeller motors, another factor enters which makes parallel operation difficult, even with d-c. machines. This is explained below.

For a drive of any appreciable size, the best results are obtained by isolating the propulsive equipment so that immediate maneuvering can be done without affecting non-related circuits. Therefore, having an isolated plant for propulsion only, voltage control is obviously the method to use.

With parallel operation of generators, voltage control is not simple of accomplishment. To vary satisfactorily the voltage of two or more generators simultaneously over the full range from zero to maximum, necessitates very closely and very carefully adjusted field rheostats, generators with practically identical saturation curves, and engines with practically identical regulation; or, some complicated and delicate automatic voltage balancing instrument.

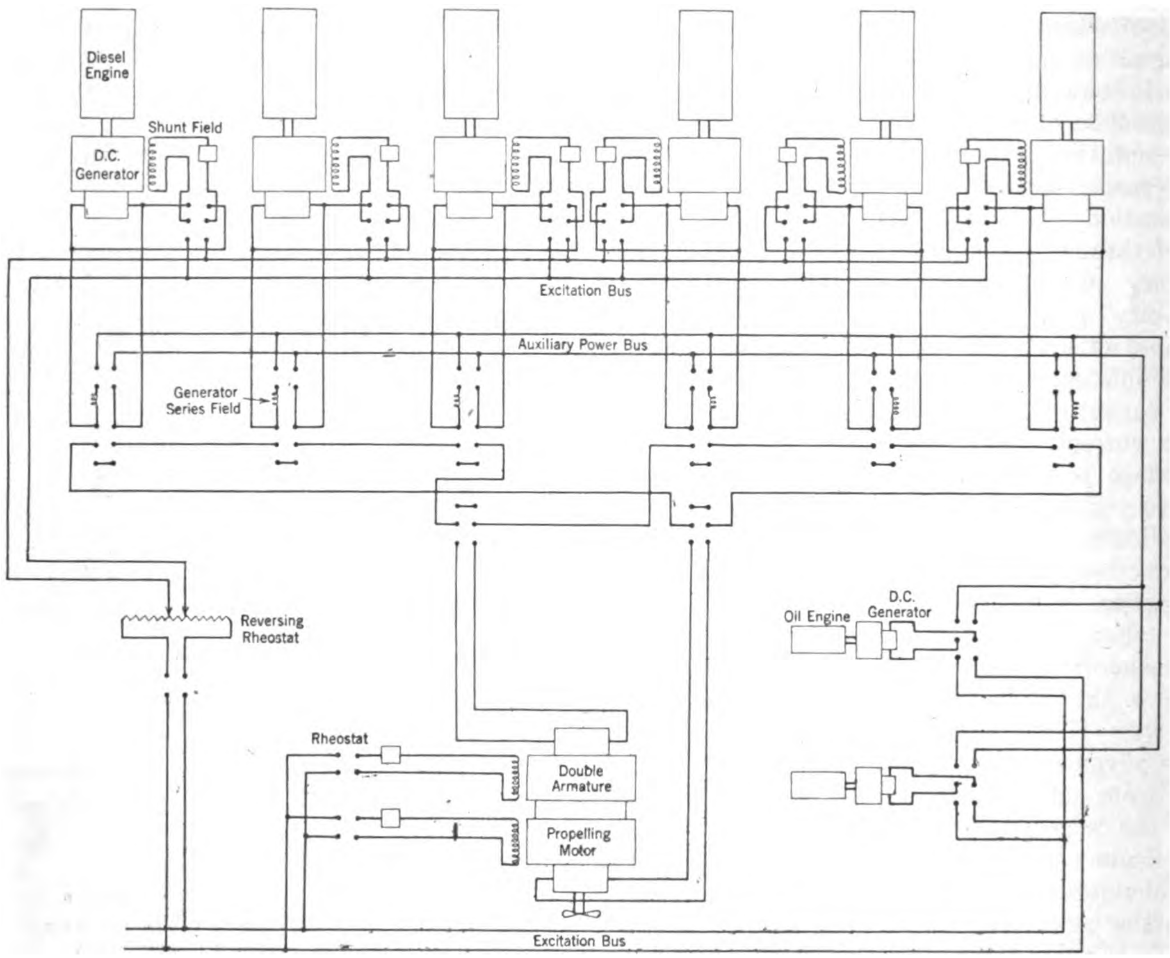

FIG. 5—DIESEL ELECTRIC DRIVE
Diagrammatic scheme of connections.

With direct current, we have a choice between two methods of motor speed control, *i. e.*, armature rheostatic and generator voltage control. Armature control is not only unjustifiably wasteful at reduced speed operation, but also adds complication to the control. On the other hand, the voltage control method is practically 100 per cent economical and provides an ease and a flexibility of control unapproachable by other systems. In the case of very small drives, armature rheostatic control might be selected because of factors not related to the propulsive equipment making it preferable to have a constant voltage system which is common to the propulsion and auxiliary circuits.

The series arrangement of generators, however, is ideal from every standpoint such as operation, control, economy, simplicity, flexibility, reserve, etc. The series arrangement, in eliminating parallel operation of generators, obviates the necessity for close regulation and hence simple engine governors and simple field rheostats are entirely satisfactory. In other words,

satisfactory operation is independent of variation in voltage between the different generators.

Besides the operating advantages, the series arrangement inherently provides for full power from each of the remaining generators in case of casualty to one or more of the generating sets without providing additional capacity, and consequently additional weight in the motor. To obtain full power from each of the remaining sets with parallel operation would necessitate increasing the motor field in order to lower its speed to such a value as would require the total capacity of the remaining units, thus necessitating a larger and heavier motor.

Fig. 5 shows a diagrammatic scheme of connections for a single-screw Diesel-electric drive. In this particular case, there are six generating sets and one double-unit direct-connected motor. The six generators and the two motor units are connected in series. The machines are distributed electrically as follows: three generators, one motor unit, three generators and one motor unit, to reduce the voltage strain, or the maximum voltage to ground at any two points to one-half the total voltage of the system. The voltage of each generator being 250, we have in effect a 1500-volt system with only 750-volt insulation requirements. The advantages of this arrangement are obvious, especially in the case of large capacity drives and where there are several generators involved. The diagram shows an arrangement for using as many as may be desired of the main generating sets for supplying power to the ship's auxiliaries when in port. Although the generators (and motors) operate as pure shunt machines when driving the ship, series windings on the generators are automatically placed in circuit when the generators are connected to the auxiliary bus, and therefore, the generators operate as compound machines when supplying the auxiliary load, and when used for this purpose the generators are operated in parallel. Arranging the generators for supplying power to the ship's auxiliary bus determines the voltage of the individual machines (250 volts).

The motors and generators being pure shunt-wound machines, the motor speed is adjusted to any value within the requirements by the voltage control system. In this system, the generator and motor fields are separately excited (preferably from the same excitation source). The motor fields are excited at constant potential, and in one direction, whereas the generator field excitation is varied to obtain the motor speed desired. With this arrangement, the speed of the motors is directly proportional to the generator voltage and, therefore, any motor speed from zero to the maximum in either direction is obtained by merely manipulating the generator field rheostat (a common rheostat is used for all generators). Since the rheostat handles only the generator field current which is 1 per cent to 1½ per cent of the generator rating, the simplicity and economy of the control is obvious. With the type of rheostat used, the excitation of the generators may be varied from full excitation in one direction to full excitation in the opposite direction, without opening the field circuit, and therefore, the ship can be brought from full speed ahead to full speed astern without opening a single circuit.

Reserve power in the event of casualty to prime movers is greater with this type of drive than with any other. On the basis of the power varying as the cube of the speed, a three-engine unit Diesel-electric ship can make 88 per cent speed with two generators and 70 per cent speed with one generator.

The Diesel-electric has the greatest range of application of any of the economical drives (geared turbine and turbine-electric not excepted). Because of the inherent merits of this drive, it is very suitably applied to merchant ships, barges, river-boats, lake boats, ferry boats, small coast-wise vessels, yachts, fishing boats, coast guard cutters, cable laying ships, and any ship within its capacity requiring refined control and economical operation over a wide range of speed.

As compared with any type of steam drive, the principal advantages of the Diesel-electric are:

Fuel consumption,

Weight,

Control,

Considerably more reserve power in case of casualty to prime movers.

The principal advantages of the Diesel-electric drive as compared with direct Diesel drive are:

Reliability. Cylinder parts being thinner are not subjected to such high temperature strains in heads and liners as are the large low speed engines, and conquently, there will be fewer breakages of these parts. Years of application and service demonstrate beyond a doubt the full reliability of electrical machinery.

Maneuvering Ability and Control. The control is extremely simple, easily understood, and can be placed anywhere on the ship. The engines run at constant speed and hence the engine reversing gear is eliminated.

Weight. On a very conservative basis, the Diesel-electric should show at least 100 pounds less per propeller shaft horse power.

Propeller Application. Propeller speed not restricted, and in the case of large ships, one propeller would be used for Diesel-electric, whereas, because of engine conditions, two would be used with direct Diesel.

Reserve Power in Case of Casualty. Very much greater with the Diesel-electric.

Maintenance. For reasons under "Reliability", the maintenance should be less. Furthermore, due to smaller parts and reserve power, repairs to Diesel-electric engines can usually be made on board ship while under way, providing sea conditions permit. The engines for Diesel-electric are designed and built on the same conservative basis as direct-drive Diesels, and are not the high-speed, short-lived submarine type.

Less Starting Air. Diesel-electric requires starting air only during the initial start in port. Subsequent engines may be started electrically. No air is used during reversing and consequently, the air problem is reduced to simplest terms.

Fuel Consumption. There would be little difference in the net fuel oil and lubricating oil consumption as the increased efficiency of screw and the reduced strutt losses, with the low-speed single-propeller Diesel-electric, offset the twin-screw arrangement of the direct Diesel. From a standpoint of piston speed, the engines used for Diesel-electric drive are no different than direct-connected engines. (The former exceeds the latter only in *revolutions per minute*).

Cost. The cost of Diesel-electric in some cases is less than the cost of direct-connected Diesel drive on present day figures, and will generally show a greater gap when fully developed along standardized lines.

General Summary for Merchant Ship Electric Drives

In the way of a summary relative to all types of electric propulsive equipments for merchant ships, the following salient features may be reviewed:

1. Electric drive is as reliable as any drive suitable for ship propulsion.
2. Maintenance and repairs should not exceed those of other drives, and in some cases should show a saving.
3. Electric drive is ideal for ship propulsion, and will soon be recongized (if it is not already recognized) as a standard type along with the reciprocating engine, geared turbine and Diesel engine drives.
4. Electrical machines have longer life than engines or geared turbines (drives) and do not decrease in efficiency with age.
5. Electric drive (Diesel-electric) is as reliable as any economical drive generally; weighs less than any other drive; is as economical as the best; in most cases costs less than any other drive;* provides more reserve power in case of casualty to prime movers; and affords simplest and most flexible control.

War Vessels

The electric propulsive equipments for war vessels have been described and discussed in many articles in the technical press, and therefore, only the principal phases will be dealt with here.

The fact that the last nineteen capital ships of the U. S. Navy are, or will be equipped with electric drive, is sufficient testimony in behalf of what the builders and users of war vessels think of its merits. The prime requisite of reliability in any type of machinery designed to propel war vessels was recognized in the electrical machinery at the time of the first installation. Also the calculations showed that the unit fuel consumption over a wide range of operating speeds should be better than anything yet proposed. Service operation of two 30,000-h. p. electrically propelled battleships has indisputably proved that the reliability is all tath was claimed, and that the fuel economy as compared with other ships of the same type using direct-connected turbines with geared cruising turbines, is vastly superior.

*It is predicted that future developments will bring the item of cost below that of any other drive.

Two other factors in which the electric drive shows a marked improvement over other drives, have been emphasized since the first battleship was built, namely, the superior protection from torpedo attack afforded the machinery by virtue of the arrangement of the electric plant, and the superior maneuvering qualities of the electric drive. The large horse power requirements of the present war vessels (60,000 h. p. and 180,000 h. p.) preclude the use of reciprocating engine drive, and this leaves electric drive with a decided maneuvering advantage over any other form of turbine drive.

Of the two types of electric propulsive equipments, only the turbine-electric is suitable for propelling war vessels, because of the large capacities required. The nineteen drives installed and building employ essentially the same system in that induction motors are used in all cases. In details, the systems differ in regard to the type of induction motor. Of the three ships in service, (the *Maryland* having been recently commissioned), the *New Mexico* motors have the double squirrel-cage rotor winding, the *Tennessee* motors have the form-wound rotor with external starting and maneuvering resistance, and the *Maryland* motors have combined single squirrel-cage and form-wound rotors. Each of these arrangements has its advocates. However, continued service alone will decide which method is the most suitable, all factors being considered.

Because of limitations in weight and space factors, electric drive is not well suited to small, high-power, fast craft such as destroyers and scout cruisers. In the case of ships where conditions are suitable for electric drive, the following dicussion of the more important factors will be of interest:

Reliability

In all phases of the industrial field where electricity has entered, it has proved its reliability. With a good record for reliability behind it, electricity has set out to establish a similar record on the sea, and the experience of the two large battleships thus far equipped with electric propelling machinery, and in service, shows that there will be a duplication of past satisfactory performance. The electrical machinery will be found to be in good condition long after the ship has become obsolete.

The arrangement of units and distribution of power make it possible to supply balanced power to all screws in the event of casualty to one of the prime

movers. In other words, the electric drive possesses an inherent advantage in regard to reserve power.

Economy

Regardless of calculations, the recorded performance of the electrically propelled battleship *New Mexico* has proved the superiority of the electric battleship in respect to fuel consumption. Recently published figures in the *Marine Review* show that the *Idaho* and *Mississippi* use 20 per cent more oil at 10 knots than the *New Mexico*; 42.7 per cent more at 13 knots, 48 per cent more at 16 knots, 40.1 per cent more at 19 knots, and 32 per cent more at full power. This superiority in fuel consumption is not altogether due to the main units, as the figures include the oil consumed by the auxiliaries. There is enough difference, however, to show conclusively that the comparison is very favorable to the electric ship.

To show that the advantage in fuel consumption demonstrated by the *New Mexico* is not a mere incident, it is well to note that the *Tennessee*, which is a later ship, is showing even better results than the *New Mexico*, as was indicated when the two ships steamed together during recent maneuvers of the Pacific Fleet. Accurate measurement of unit fuel consumption during the official trials of the *Tennessee* showed that the actual steam consumptions were less than the guaranteed figures by amounts varying from 3 per cent to 8 per cent approximately. Thus the art of electric propulsion is still progressing. The answer is found in the use of only a sufficient number of turbines for the load conditions, and in the two-speed motors, the combination of which maintains a higher average load on the turbines at a higher average speed.

Maneuvering

Owing to the availability of full backing power in the case of the electric drive ship, the latter possesses

a marked advantage over the turbine ship in maneuvering qualities. As these were referred to under "Merchant Ships," it is sufficient merely to mention at this time that electric battleships can be stopped in considerably less time than is required to stop a turbine ship. The advantage of this feature is obvious in the case of a war vessel. This is due to the combined action of quicker "set-ups" and greater backing power.

Further maneuvering advantages of the electric drive are apparent from recent publications. These advantages are chiefly concerned when entering and leaving ports and maneuvering therein. By operating the ship from one turbine set, the other, or others if there are more than two, can be held in readiness for immediate service in case of necessity such as would arise from a mudded condenser or other cause. When maneuvering to get under way, operation from a single generating set inherently enables exactly the same speed—but of opposite direction—to be obtained on the port and starboard screws. This is very desirable for the reason that the ship can be turned on its heel without making any headway. With different prime movers supplying power to the various screws, it would be difficult to maintain all the screws at the same speed and thereby turn in the same space.

Control

The control for the propelling machinery is centralized in one compartment and can be easily arranged to be operated by one operator. The flexibility of the control is such that almost any emergency resulting from casualty to any equipment connected with the propulsive machinery proper, can be taken care of in brief time by disconnecting the disabled unit from the source of power.

Maintenance

The maintenance and repairs should show to advantage because of the inherent reliability of electrical machines and the absence of wearing parts. Repairs of considerable magnitude can be made aboard the ship without removing the machinery. It is difficult to imagine a casualty to any one of the electrical units which could not be repaired on board the ship if circumstances warranted it.

Study of Performance

The electrical instruments enable accurate and convenient observations to be made of the performance of the screws at any instant. The electrical instruments also provide a means for quickly detecting improper performance of the screws due to excessive shaft friction or damaged blades. The performance of all units as indicated by the instruments is under the observation of the watch officer and control-room attendants at all times.

TELEGRAPH AND TELEPHONE NOTES

The committee on Technical Training, Telegraph and Telephone Section, American Railway Association, is planning organized instruction for communication department employees. The committee also has in view cooperation with established engineering schools looking to improvement in the character of instruction given students who aim to enter communication service.

Brigadier General Edgar Russel, chief signal officer, 2nd Corps Area, New York, will spend several months at Camp Knox near Louisville, Ky., on official duty.

The research department of the Radio Corporation of America, under the direction of Dr. A. N. Goldsmith, has recently made important improvements in tape recording receiving systems for transatlantic radio signaling.

The Morris Liebmann Memorial Prize, for the year 1921, has been awarded to Raymond A. Heising, of the Western Electric Company, New York, for his analysis of vacuum tube action and his research work on modulation systems. The prize is awarded by the Institute of Radio Engineers.

The wide extension of radio broadcasting service from a number of centers throughout the country, by means of which news items and musical concerts are given by radio telephony, has created a large demand for radio receiving equipment.

The Telegraphy and Telephony Committee of the Institute held a meeting at Institute headquarters recently at which a tentative program was made up of papers to be presented or published during the coming year. It is likely that the committee will be assigned a place on the program of the Midwinter Convention for the presentation of papers on communication engineering. Subjects of papers now being prepared, and subjects proposed, are:

Submarine Cable Telegraphy.

Key West-Havana Telegraph and Telephone Cable.

Solution of Problems Relating to Suspended Wires and Cables.

Relation of Track Signaling and Communication Engineering.

The Engineering Features of Telegraph Traffic Handling.

Engineering Features of Radio Broadcasting.

Shielding Effect and Wind Pressure Observed on a Ten-Wire Experimental Telegraph Line at Elizabethport, N. J.

Installation of an Automatic Telephone Exchange in New York City.

Printing Telegraph Systems in Use on American Lines.

A Frequency-Bridge

An Apparatus for Accurate Determination of Frequency, by Means of a Null Method

BY EDY VELANDER

Kraftverksförvaltningen, Stockholm, Sweden.

As long as there was not available in the labaratory any convenient source of alternating current of a satisfactory steadiness and purity, the technique of measurements had to confine itself to such alternating-current bridge-methods where the balance is independent of frequency, so that accidental changes in frequency do not seriously affect the setting, and a reasonable amount of harmonics does not prevent an accurate adjustment. The steadiness and purity of the output from a properly adjusted triode oscillator, however, makes it possible, in a modern laboratory, to take up and successfully apply many convenient methods of measurement, which although known since many years, have been discarded and forgotten for reasons suggested above. On the other hand it enables us to utilize new methods, where the frequency enters explicitly into the result.

It then becomes necessary, however, to provide means for rapid and precise determination of the frequency employed, respectively for the accurate adjustment of this frequency to a predetermined value. With these points in mind the writer undertook to work out a zero-method for measuring frequency, and developed an arrangement which may be called a frequency-bridge.[1] This frequency-bridge has since been extensively used, and while it is particularly suitable as standard for frequency measurements in the audio range, it has also been successfully used for measuring frequencies of the order of 60 cycles.

Strictly speaking, any alternating-current bridge arrangement, where the balance is in any way affected by the frequency of the applied current, could be conversely used as a frequency-bridge. Of all possible arrangements, however, those will give the highest sensitivity, where the balance is based upon a comparison of the voltage across a condenser with the drop across an inductance, or with the induced e. m. f. in the secondary of a mutual inductor. A condensive and an inductive drop will be affected by a change in frequency in just opposite ways, and the balance will therefore be doubly sensitive.

The Campbell Mutual-Inductance-Condenser Method

A method, based upon these principles, was suggested by G. A. Campbell[2], who later[3] proposed certain modifications of the same. In the original Campbell arrangement, a condenser C is connected in series with the primary of a mutual inductance standard M, in the way Fig. 1 indicates, the drop across the condenser C being compared with the mutual reactance drop in the secondary coil by means of a zero-indicator T, for instance a pair of head-phones, or a vibration galvanometer. If I is the primary current, we get, by equating to zero the total drop along the indicator-mesh, and assuming that no current flows in T, the following complex equation for a balance:

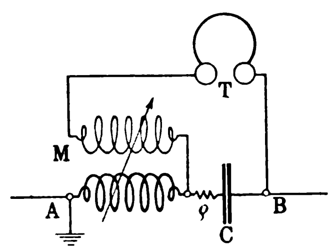

Fig. 1—The Campbell Mutual-Inductance Condenser Method for Measuring Frequency

$$I \,.\, j\,\omega M + I\left(\rho + \frac{1}{j\,\omega C}\right) = 0$$

This is equivalent to two actual conditions of balance:

$$\begin{cases} \omega = \dfrac{1}{\sqrt{MC}} \\ \rho = 0 \end{cases}$$

Since ρ here denotes the equivalent series resistance of the condenser, the last equation indicates that a "perfect" condenser should be used in order to get a clean balance. A condenser of unusually small losses therefore is necessary for refined work, unless some special scheme is used for advancing the phase of the mutual-inductance drop in the secondary.[3] Another difficulty is that the method calls for a con-

1. The frequency-bridge has been briefly described, in a paper on "Rectangular-Component, Two-Dimensional Alternating-Current Potentiometer" by A. E. Kennelly and Edy Velander, *Journal Franklin Institute*, July, 1919, also *Bulletin No. 18*, of the Electrical Engineering Research Division, of the Massachusetts Institute of Technology.

2. G. A. Campbell, *Philosophical Magazine*, 15, 1908, p. 166, and *Proceedings of the Physical Society*, 21, 1908, p. 80.

3. G. A. Campbell, *Electrician*, 80, 1918, pp. 666-667, also *Proceedings of the Physical Society*, 29, 1917, pp. 345-353.

denser and a mutual inductance of such demensions that $M\,C$ is equal to the inverse of ω^2. In measuring low frequencies the product of M in henrys and C in microfarads therefore must be rather large, at 60 ~ about 7, necessitating the use of very large coils, and a condenser of rather high capacity. We understand, however, that the method has been used with much success by Dr. Campbell for accurate calibration of frequency meters in the commercial frequency range.

The Compensated Frequency-Bridge

It was found that by certain modifications of this mutual-inductance-capacity arrangement, it is possible to eliminate both the mentioned disadvantages without introducing too much complication. Several different schemes for this purpose were tried out, and finally the arrangement shown in Fig. 2 was selected as the apparently most satisfactory.

The series-arrangement here is shunted by a resistance R of a few thousand ohms, and the drop across the nth part of this resistance is compared to the mutual-reactance drop in the secondary coil. A small inductance l must be inserted in series with the resistance R, as will be presently seen.

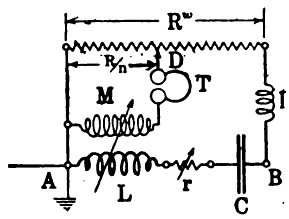

Fig. 2—The New Form of Frequency Bridge

Now, if we assume that no current flows in the indicator T, and if we let V_{AB} denote the voltage across the entire arrangement, then the drop from A to the tap D will be

$$V_{AB} \times \frac{\dfrac{R}{n}}{R + j\,\omega\,l}.$$

The current in the condenser branch is

$$I_C = \frac{V_{AB}}{r + j\,\omega\,L + \dfrac{1}{j\,\omega\,C}}.$$

In r is included the primary coil resistance and also the equivalent series resistance of the condenser. L is the primary inductance. The induced electromotive force in the secondary will be $-j\,\omega\,M\,I_C$, and we get as a condition for balance:

$$V_{AB} \times \frac{\dfrac{R}{n}}{R + j\,\omega\,l} - V_{AB} \times \frac{j\,\omega\,M}{r + j\,\omega\,L + \dfrac{1}{j\,\omega\,C}} = 0.$$

This equation may be broken up into the following two expressions, corresponding to real and imaginary parts:

$$\begin{cases} \omega = \dfrac{1}{\sqrt{C\,(L + n\,M)}} \\ l = R\,r\,C\left(1 + \dfrac{L}{n\,M}\right) \end{cases}$$

The formula for the frequency thus is very simple and easy to remember due to its analogy with the expression for the resonant frequency in a condenser-inductor circuit. The effect of the potentiometer arrangement of R evidently is to multiply the effect of the mutual inductance in the ratio n to 1. If n is chosen reasonably large, say about 20, a balance may therefore be obtained with coils and condensers of reasonable dimensions, even if the frequency to be measured is rather low.

The second equation shows that the small inductance l is necessary for a clean balance. It serves to retard the phase of the current in R the same amount as the current in the condenser is retarded behind the 90-deg. leading position by the resistance r in the main branch. In any practical case the necessary amount of inductance is very small, and it will be found that the adjustment corresponding to the last equation really has the nature of a balance refinement. The bridge therefore will work satisfactorily even if the last condition is only roughly adjusted for.

The Frequency-Bridge in Practise

In practise there are several ways of obtaining a frequency balance with this arrangement. Usually it is most convenient to employ a condenser of a fixed value, and to vary the value of M, or the ratio n. A Campbell mutual inductometer is very convenient as a variable mutual-inductance standard, but for less precise work an ordinary variometer may be used. If such a continuously variable mutual inductor is available, one fixed ratio n is sufficient. A non-adjusted ratio box may easily be made up for the purpose, and the ratio accurately determined with direct current. Since a certain amount of inductance is always introduced in series with the resistance R, it is obvious that at least the bigger one of the ratio resistances need not be non-inductively wound. In fact, it is easy to show, that a reasonable amount of inductance even in the smaller ratio resistance has no detrimental effect upon the accuracy of the bridge.

If no variable mutual inductor is available, a pair of coils with a fixed value of mutual inductance may be used. In this case the variation should be made in the bigger ratio arm, which then conveniently is made up of a decade resistance box of sufficiently fine steps.

If a wide range of frequencies must be covered, it is advisable to provide at least two steps in the condenser. A good method is to have two equal condensers which

may be connected in parallel or in series. The calibration of the instrument then will be altered exactly in the ratio 1 to 2, since the capacity when changing the condenser connections is altered in the ratio 4 to 1.

The condensers need not be very accurately adjusted. Assume, for instance, that their capacities are c_1 and c_2 and let us denote their arithmetical mean by c_0. We may then write

$$\begin{cases} c_1 = c_0\,(1+\epsilon) \\ c_2 = c_0\,(1-\epsilon) \end{cases}$$

For parallel connection the capacity evidently will be $C_p = 2\,c_0$, and for the series case we obtain:

$$C_s = \frac{c_0\,(1+\epsilon) \times c_0\,(1-\epsilon)}{c_0\,(1+\epsilon) + c_0\,(1-\epsilon)}$$

or

$$C_s = 1/2\,c_0\,(1-\epsilon^2)\ .$$

The ratio of C_p to C_s then will be

$$\frac{C_p}{C_s} = 4\,(1-\epsilon^2)$$

and thus

$$\frac{f_s}{f_p} = 2\,(1 - 1/2\,\epsilon^2)\ .$$

Hence, if the relative deviation in capacity between the two condensers, or $2\,\epsilon$, is as much as 2 per cent, the error in assuming that the calibration changes exactly in the ratio 2:1 will be only five parts in one hundred thousand, a quantity which for ordinary work is entirely negligible. Even if the capacities are as 9 to 11, the error is only one-half of a per cent.

The auxiliary adjustment in l, corresponding to the equation

$$l = R\,r\,C\left(1 + \frac{L}{n\,M}\right)$$

is most easily obtained by winding up a small coil of fixed inductance of a little bigger value than required, while a fine-adjustment is made on a small resistance in series with the primary coil L. This resistance should have rather fine steps, but need not be calibrated. It should have a maximum value approximately equal to the resistance of the primary. The resistance of the small auxiliary coil l must of course be accounted for in determining the ratio n.

In order to secure a high sensitivity the balance indicator should have an impedance of the same order as the impedance of the secondary of the mutual inductor plus the smaller ratio resistance R/n. An ordinary low-impedance vibration galvanometer therefore gives very good sensitivity with the described bridge. The most convenient balance indicator, however, is a pair of telephones, but for good sensitivity a pair of low-impedance receivers should be selected, and the mutual inductor should be wound with many turns on the secondary and few on the primary. (This has the additional advantage of giving a low value of r, and thus reducing the importance of the auxiliary adjustment in l.) A fairly good sensitivity sometimes may be obtained also with receivers of high resistance, if a good step-up telephone transformer of suitable ratio of transformation is interposed.

A Wide-Range Frequency-Bridge

A convenient form of long-range frequency-bridge, embracing the entire telephonic frequency range, is shown in Fig. 3. An alternating current of a few milliamperes of the frequency to be measured is passed through the bridge from A to B. It is desirable to ground the point A so as to avoid disturbances from spurious capacity currents. C is the standard condenser, made up of two clamped mica units, adjusted within per cent to a capacity of 0.4 microfarad. These units may be connected either in series, by plugging as indicated by full dots, or in parallel as shown by small circles. The working capacity thus is either 0.2 or 0.8 microfarad.

L is the primary coil, with a small auxiliary fine-step resistance σ in series. The secondary coil M is shown to have three fixed subdivisions, $a-b$, $b-c$, and $c-d$. Each is adjusted to about 2.5 millihenrys mutual inductance, and one, two, or all three of them may be connected in series by turning the handle I. A rotating, fine-adjustment coil is provided, which gives a continuous variation from 0 to 2.5 millihenrys. By dividing the fine-adjustment coil into two equal subdivisions, one fixed, and one rotating, the scale from 0 to 2.5 millihenrys may be made to embrace a 180-deg. angle thus permitting a very accurate setting. The rotating part of the fine-adjustment coil is manipulated by the handle II.

The smaller ratio resistance, which corresponds to R/n above, is kept fixed at 100 ohms, but the value of R may be set at 500, 2000, or 8000 ohms by turning the selector switch III. This gives three values of n, namely 5, 20, and 80, which stand to each other in the ratio 1:4:16, corresponding to changes in frequency range approximately as 1:2:4.

As shown by the formula above, l is, for a constant value r, approximately proportional to the product $R\,C$ (since $\frac{L}{n\,M}$ is a small quantity in comparison to unity). Thus four values of l must be provided, corresponding to the four possible values of $R\,C$ which range from $500 \times 0.5 \times 10^{-6}$ to $8000 \times 0.8 \times 10^{-6}$. This is accounted for by four taps on the coil l, roughly adjusted to give inductance values corresponding to these four values of $R\,C$. The total resistance introduced by the auxiliary coil is for each tap adjusted to a certain convenient value, say ρ ohms, and to compensate for this increase in resistance in the R-branch, the second unit in this branch, which should have had the resistance 400 ohms, if the coil l had had no resistance, is instead adjusted to $400 - \rho$ ohms.

The selector-switch III automatically picks out the right tap on l when the desired R-value is connected. However, since there are two possible values of capacity for each step in R, a double-point system must be used, as shown in the figure, allowing for the six possible combinations of R, C and l.

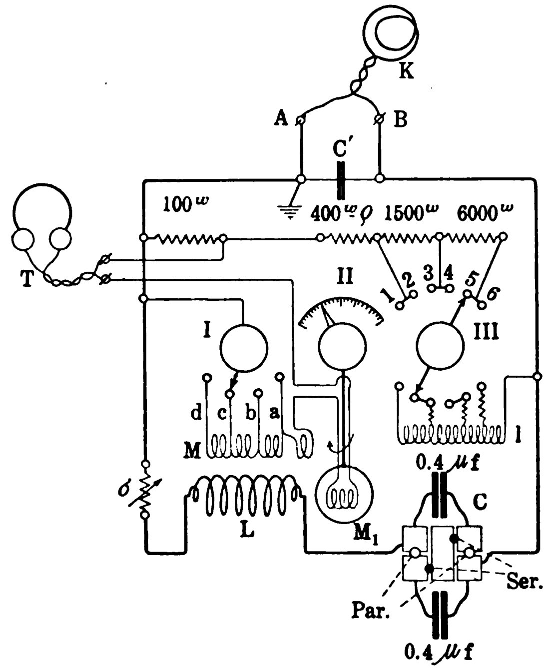

FIG. 3—COMPLETE WIRING DIAGRAM OF A LONG-RANGE FREQUENCY BRIDGE

With a variation of M from approximately 2.5 millihenrys to 10 millihenrys, we obtain with this bridge the following frequency-ranges:

Position of Switch III.	R ohms	Condenser:	n M C $m\,h\,.\times\mu f$	Frequency
1	500	series	2.5—10	3200—1600
2	500	parallel	10—40	1600— 800
3	2000	series	10—40	1600— 800
4	2000	parallel	40—160	800— 400
5	8000	series	40—160	800— 400
6	8000	parallel	160—640	400— 200

As seen from the table, there are in the middle of the working range two possible settings for the measurement of each frequency value. Usually one or the other will give a clearer balance. If it should so happen, that the condenser arm, at the frequency to be measured, gives resonance with the supply coil for one of the harmonics in the supply voltage, this harmonic will be accentuated, and disturb the balance. By changing the condenser setting, however, the undesirable harmonic usually may be cut down to normal size. The bridge naturally is rather sensitive to impurities in the wave form, and sometimes, when a telephone is used as an indicator, it is necessary to employ some filtering arrangement, either on the supply side, or in the telephone leads, or both. The condenser C, on Fig. 3, of a few tenths of a microfarad capacity, represents a rudimentary electric filter, and often improves the balance materially by serving as a by-pass for overtones. Sometimes it is better to insert a variable condenser instead of C and tune up the supply circuit, with the coupling coil K, to resonance for the fundamental. A simple filtering scheme which has proved rather useful at frequencies in the neighborhood of 1000 ~ is shown in Fig. 4. The coils used were ordinary iron-cored telephonic loading coils. The difficulty in designing a filter for a long-range frequency-bridge naturally is the necessity of making the cut-off point of the filter adjustable.

The entire frequency-bridge, as shown in Fig. 3, may be built into a box, if proper care is taken to avoid mutual inductance between the main mutual inductor and the compensating device l. The instrument then becomes a portable, completely self-contained unit, with only four binding-posts, two for the supply, and two for connecting the indicator, telephones or vibration galvanometer, as the case may be. If the steps b, c, d are omitted, the movable coil may be graduated directly in frequency. It then is advisable to use a somewhat larger fixed secondary coil in series with the rotating coil, so that the full range of 180 deg. on the latter will correspond to a mutual inductance change in the ratio of 1 to 4. By placing the coils so as to give a proper distortion of the mutual-inductance calibration, a reasonably even frequency scale may be obtained. With a series-parallel connected pair of condensers a frequency-range of, say, 500-2000 ~ thus may be covered on one double-reading scale of 180 deg. angle.

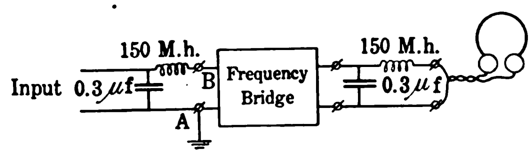

FIG. 4—FILTERING ARRANGEMENT USED WITH THE FREQUENCY BRIDGE

The frequency-bridge as described above gives a remarkably good accuracy of setting. With only a few milliamperes through the bridge, and a pair of good telephones, frequencies in the audio range may easily be determined to within a fraction of a cycle, if the mutual inductor has a sufficiently fine graduation. Below 500 ~ the telephone sensitivity rapidly decreases, and a vibration galvanometer is superior.

It must be noted, however, that in this bridge, as in any other alternating-current null-method, the balance is very sensitive to stray fields, whether inducing in the secondary directly, or in the telephones themselves. In accurate work, therefore astatic coils should be used, and the telephones kept at a considerable distance from the mutual inductor.

Extension to Higher and Lower Frequencies

The bridge appears to be useful also in work at frequencies above the telephonic range. Although, at a high frequency, it is easy to fulfil the requirement $M C = 1/\omega^2$ of the simpler Campbell method, the distributed capacity of the coils used, sometimes causes difficulties, especially as in this method, the common point of the two coils in the mutual inductor must not be grounded, if correct results are required but instead the point A or B, Fig. 1, must be grounded. In the frequency-bridge here described, these inconveniences are partly eliminated, since smaller coils may be used, and disturbances due to capacity to ground may be avoided by grounding the bridge at A, Fig. 2, and Fig. 3.

In work at higher frequencies the secondary circuit should be tuned with a condenser, and a crystal- or tube-detector with a d-c. galvanometer used as a balance indicator.

In connection with some work with the rectangular potentiometer,[1] the author has used the bridge for the direct determination of frequencies in the commercial frequency range, as far down as 50 $\sim$ and lower. A triode oscillator was used as a source of supply, and the indicator was a Campbell vibration galvanometer. The constants of the bridge during these experiments were as follows: $C = 1\,\mu$ f., M = 50-100 mh., R = 8000 ohms, n = 80, l = 300 mh. (This unusually high value of l was partly accounted for by the rather large primary resistance of the 400-millihenry variometer used as a mutual inductor.)

With this arrangement it was easy to adjust the frequency to within 1 part in 5000 of a given value.

NOTES FROM THE BUREAU OF STANDARDS

Standard Radio Wavemeter

The Radio Section of the Bureau is called on to test for government agencies, commercial and university laboratories, and others a great variety of radio material, especially wavemeters. Not only in connection with radio communication, but also in a wide and growing field of electrical research, there is an insistent demand for accurate measurement of the wave length or frequency of rapidly alternating currents. In the standard wavemeter most recently designed by the Bureau, careful attention has been given to the electrical and mechanical considerations which make for accuracy, especially rigidity of construction, and precision of set and reading. This wavemeter, when calibrated, will be capable of measuring wave lengths from 65 to 85,000 meters, or in terms of frequency from 3500 to 4,600,000 cycles per second.

A typewritten description of this wavemeter has been prepared and is available for distribution to interested persons.

Standard Specifications for Large Incandescent Electric Lamps

For about 14 years electric lamps have been purchased by the federal government under specifications published in Circular 13 of the Bureau of Standards. Progress in the art of lamp manufacture has been so rapid that this circular has had to be revised eight times in order to keep the specifications abreast with current developments.

The 9th edition of this circular has just now been published and may be obtained at five cents per copy from the Superintendent of Documents, Government Printing Office, Washington, D. C. The original specifications covered only carbon filament lamps while in the later editions metallized carbon and tantalum lamps were introduced and then discarded as tungsten replaced them in use. In connection with these radical changes in types of lamps, very great improvements were made in the efficiency and the life required, but no fundamental change was made in the form of the specifications or methods of testing. However, for the fiscal year beginning July 1, 1921, new specifications have been adopted which include important changes in the test procedure for tungsten lamps. The most notable of these changes is the abandonment of the long-established provision that the life of test lamps shall be considered as ended when the candle power has fallen to 80 per cent of the initial value. Now the life is considered as the total life of the lamp since the efficiency of tungsten lamps drops but very little up to the point of burn-out. The performance of a lamp throughout its life will also be taken into account and tolerances are provided to care for possible variations in test results where only a small number of samples of any one order are available.

Tests under these new specifications are intended to give a more complete indication of the performance of lamps than was the case with the former specifications and while prepared primarily for use by the departments of the government in purchasing incandescent lamps, it seems desirable on account of the thoroughness with which the subject has been studied and discussed to make the specifications available for the general public. It is for this reason that they are being used as the 9th edition of Circular 13.

Criticisms and suggestions concerning these specifications and lamp ratings are invited from both manufacturers and users and all such suggestions will be carefully considered in the event of a further revision of the specifications.

Abnormal Voltage on Y-Delta Transformer Bank Due to Reversed Connection

BY C. R. REID

Shawinigan Water and Power Co.

THE writer recently observed some abnormal voltage conditions on a Y-delta connected transformer bank which suggested the subsequent investigations described in this paper. The transformers were rated at 50 kw., 30 cycles, 12,000/2300 volts, and were Y-connected to a 22,000-volt, 62½-cycle line. This line was fed by a bank of 50,000/13,200 volt, transformers Y-connected on the low tension side, and with grounded neutral as shown in Fig. 1.

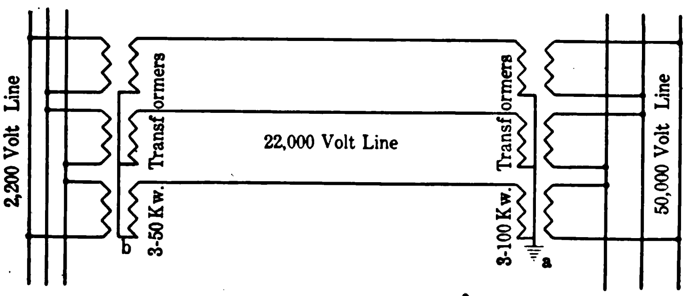

FIG. 1

Since the spare transformer was of the same type as the one it replaced, no effort was made to check its polarity before it was put into service. When the high-tension switch was closed and power put on the bank, the transformer newly connected gave out a loud humming noise and a check of the voltage on its low-tension side showed it to be something like 300 per cent of normal. A check on the connections

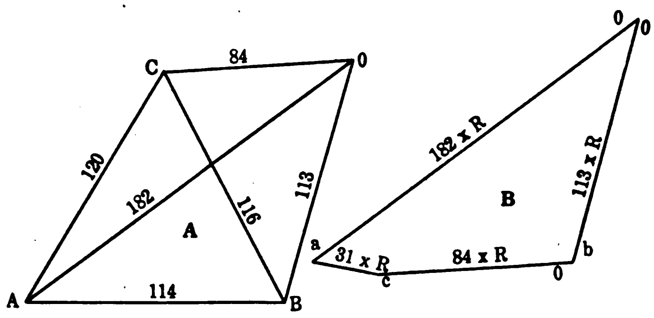

FIG. 2—BANK OF 15-WATT POTENTIAL TRANSFORMERS
A—Diagram of *Y* voltages
B—Diagram of delta voltages

showed that the transformer had been connected in with reversed polarity. When the proper connections were made, the transformer went into service without further trouble. It should be borne in mind that these were 30-cycle transformers operating on 62½ cycles. For this reason the excessive voltage did not cause undue distress.

Later on, a bank of three 6000/100-volt, 15-watt, 25-cycle potential transformers was set up in the laboratory, the 6000-volt windings were delta connected and the 100 volt windings were Y-connected, with one phase reversed, to a three-phase, 62½-cycle, 110-volt circuit. Voltage readings were taken on the low-tension side between phases and between phase wires and neutral. The following readings were obtained; *A*, *B* and *C* denoting the phase wires and *O* denoting the neutral:

A B	*B C*	*C A*	*A O*	*B O*	*C O*
114	116	120	180	115	86

A diagram of voltages was laid off as shown in Fig. 2. The phase voltages were first drawn to form the triangle *A B C* and then arcs were struck from *A*, *B*, and *C* with radii *A O*, *B O*, and *C O* corresponding to the measured values of voltage. These three arcs did not exactly meet in a point, but *O* was located at the center of the triangle formed by their intersections and the voltages *A O*, *B O*, and *C O* corrected accordingly. A triangle of secondary voltages was

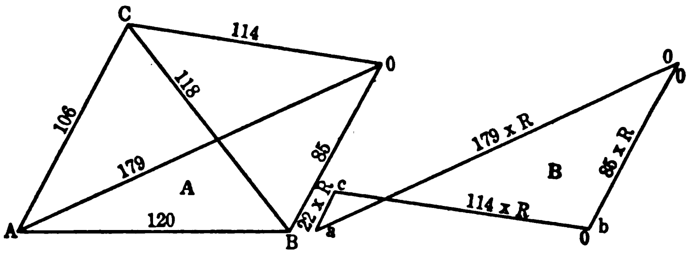

FIG. 3—BANK OF 15-WATT POTENTIAL TRANSFORMERS
A—Diagram of *Y* voltages
B—Diagram of delta voltages

laid out as shown at *B* in Fig. 2. This triangle did not close by 31 *X R* volts, indicating a circulating current in the delta. An ammeter connected in the delta showed a circulating current of 0.19 ampere.

Two of the 110-volt supply leads were reversed in order to change the phase rotation. Readings were then taken as follows:

A B	*B C*	*C A*	*A O*	*B O*	*C O*
120	118	106	178	86	115

From these readings a voltage diagram, (Fig. 3) was made up. By an inspection of Figs. 2 and 3 it is apparent that the phase rotation was responsible for the displacement of the neutral point *O* to one side of the axis of symmetry of the diagram.

In order to decrease errors due to high reactance a test was made on a bank of 5000-kw., 60-cycle, 6600/57,800-volt transformers. This bank was delta connected on the low-tension side and Y-connected on the high-tension side with the polarity of one trans-

former reversed. A 200-volt, 62½-cycle, three-phase circuit was connected to the high-tension winding and the following readings obtained:

AB	*BC*	*CA*	*AO*	*BO*	*CO*
190	190	190	320	180	180

A diagram was constructed from these voltages, (Fig. 4). This diagram shows that there was no displacement of the neutral point due to phase rotation. In fact, a set of readings taken with opposite phase rotation gave identical results. The resultant voltage in the delta was 13 *X R* volts and consequently the current circulating in the delta must have been quite small, though no attempt was made to measure it.

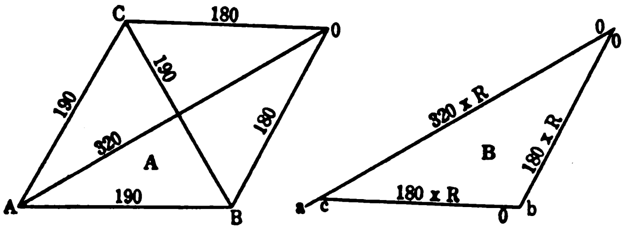

FIG. 4—BANK OF 5000-KW. TRANSFORMERS
A—Diagram of *Y* voltages
B—Diagram of delta voltages

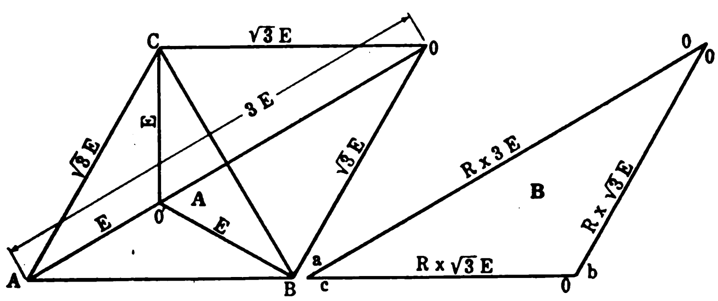

FIG. 5—THEORETICAL VOLTAGE RELATIONSHIPS
A—Diagram of *Y* voltages
B—Diagram of delta voltages

Fig. 5 is a diagram of the theoretical voltage relationships for the primary and secondary. This diagram fulfills the conditions that the three primary voltages to neutral when plotted should meet in a point; and that the three secondary voltages, (which must of course be plotted parallel to and proportional to the primary voltages), should form a closed triangle, *i. e.*, have no resultant voltage. These conditions will be modified in actual practise by the differences in the characteristics of the transformers, and also by the excessive magnetizing current in the transformer of reversed polarity.

It is possible that some use might be made of this connection for applying a voltage test to a transformer or to obtain a desired voltage. It may be interesting to note that by increasing the delta voltage of the reversed tranformer by changing its ratio, the neutral point *O* on the diagram is still further displaced, approaching infinity as the ratio of the reversed transformer approaches twice that of the other two.

Later on, a case of a wrong connection was reported on a system identical to that shown in Fig. 1. In this case, however, the reversed transformer was at the sending end of the line. The results noted were reversal of phase rotation and low voltage. The low voltage was very marked on one phase when no motors were running, but the operation of motors served to boost the voltage on this phase.

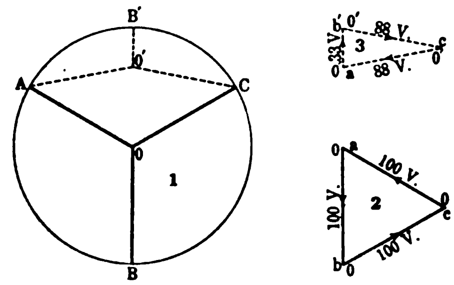

FIG. 6—VOLTAGE DIAGRAMS FOR *Y*-DELTA TRANSFORMER BANK AT RECEIVING END OF LINE
1—*Y* voltages
2—Normal delta voltages
3—Delta voltages when one transformer is reversed at sending end of line

Apparatus was set up in the laboratory to reproduce the above conditions and data obtained to construct voltage diagrams. The theoretical voltage relations for the transformer bank at the receiving end of the line are shown on Fig. 6. These values were very closely approximated by the laboratory test. A study of the voltage diagram for the delta-connected side shows that the phase rotation is reversed and that the voltage is 33 per cent normal on one phase and 88 per cent normal on the other two.

INCREASED TELEPHONE SERVICE IN ATHENS

At the present time a central board serves 1600 telephone subscribers in Athens. This is now found to be insufficient to meet the increasing demands of subscribers, and a committee of technical experts appointed by the Greek Ministry of Communications has recommended the installation of a central board capable of serving 10,000 telephones.

The committee recommended also that subterranean cables be laid to do away with the overhead wires. Inasmuch as the committee believes that four years will be required to complete this work, it has advised that, to meet the emergency, the present system of overhead wires be continued and the board increased from 1600 to 5000 telephone connections, and for this purpose has asked for bids. At the same time bids are requested for the larger central station, which will accommodate 10,000 subscribers. The bids must be submitted to the Ministry of Communications, Athens, Greece.

Commutation on Direct-Current Machines

BY CLAUDIUS SHENFER

Professor of Electrical Engineering, Technical High School, Moscow.

It is well-known, that in direct-current machines with heavy linear armature load (number of ampere conductors per cm. of armature circumference) the commutation occurs under especially heavy conditions; the reactance voltage in such machines rises to a great value and therefore each in accuracy of the compensation of reactance voltage by means of interpoles produces a great additional current in the armature coils short-circuited by the brushes, which causes sparking at the commutator.

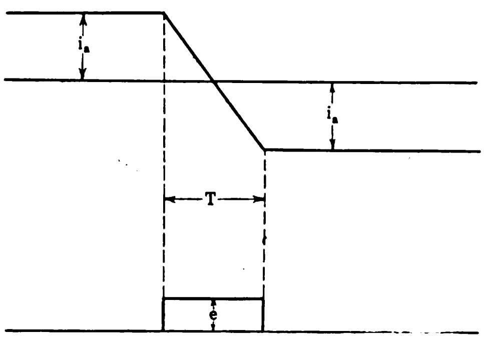

Fig. 1—Current in Armature Coil, Short-Circuited by the Brush (i_a) and E. M. F. of Self-Induction (e)

In machines of low output the reactance voltage compensation at each moment of commutation is not absolutely necessary; in many cases it is sufficient if the reactance voltage is compensated in its *mean value,* but in high-power machines with heavy linear armature load this condition of exact compensation must be fulfilled.

In that case it is necessary to know the reactance voltage curve, its maximum and minimum value, short-circuit time, current per cm. of armature circumference, etc.; this will enable us to find the magnetic induction in the air gap under the interpole and not only its *mean value* but also its shape.

Reactance Voltage

In finding the reactance voltage value we proceed from the supposition that the current variation in the armature coils short-circuited by the brush at the moment of commutation occurs according to the "direct-line" law.

This supposition greatly simplifies the question, because the e. m. f. induced by the current variations remains constant during the whole period of commutation, as is shown in Fig. 1.

The curve of the resulting e. m. f. induced in the armature conductors in the moment of commutation greatly differs from the reactangular shape shown in Fig. 1; this depends upon the mutual induction of the conductors lying in one and the same slot and also in the adjacent slots; further on we will denote this resulting e. m. f. by "reactance voltage" in order to distinguish it from the "self-induction e. m. f." generated in the conductor by the alteration of its *own* magnetic flux.

Supposing the mutual induction coefficient for the conductors lying side by side in one slot equals 1, it is possible to find the e. m. f. induced in each conductor during the commutation, as is shown in Fig. 2; in this figure is shown, for example, the reactance voltage for a Gramme armature with three conductors in one slot; from this figure we see that at first the turn formed by conductor 1 is short-circuited by the brush, the current in this conductor varying according to the curve 1-1; after an interval of time, when the commutator has moved the distance of one commutator pitch β, the commutation begins in conductor 2, and finally after the same interval of time β, in conductor 3; the e. m. fs. of self-induction induced by the variation of its own magnetic flux in the conductor 1, 2, 3 are shown in Fig. 2 in the shape of rectangles A_1, A_2, A_3 displaced on the commutator pitch β. In order to find the resulting e. m. f. (reactance voltage) it is necessary to add the ordinates of the three curves A_1, A_2, A_3; this gives the staggered curve β—the reactance voltage curve; the curve of the e. m. f. induced in the conductor 1 is

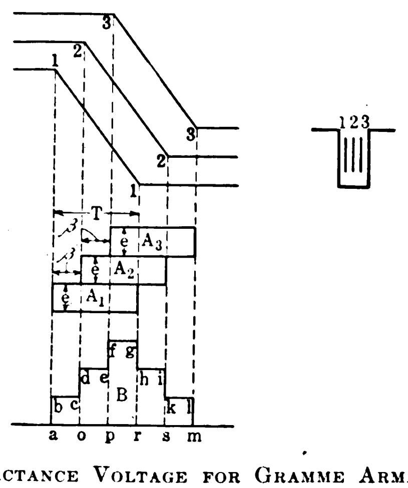

Fig. 2—Reactance Voltage for Gramme Armature with Three Conductors in One Slot (Curve B)

represented by the staggered curve: *a, b, c, d, e, f, g, r,* the curve of the e. m. f. in the conductor 2 by *o, d, e, f, g, i, s* and that in conductor 3, by *f, g, h, i, k, l, m.*

Thus the maximum value of the reactance voltage e_{mx} under the conditions shown in Fig. 2 will be: $e_{mx} = 3\,e$; the value of the e. m. f. of self-induction e may be determined in the following way. Denoting i_a the current strength in each conductor of the armature winding, L the coefficient of self-induction of the armature coil, and T the period of commutation, the e. m. f. of self-induction is $e = L\,2\,i_a/T$ (straight line commutation); inserting in the above expression

$T = b/v$, where b is the width of the brush reduced to the periphery of armature[1] and v = the peripheral speed of the armature, we get $e = L \dfrac{2\, i_a\, v}{b}$

The self-induction coefficient of one armature coil L in this last formula may be determined as follows: $L = w^2\, l . \lambda$, where l is the length of the armature iron in cm., and λ the coefficient of the slot-leakage conductivity.

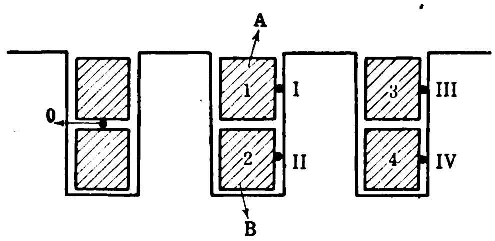

Fig. 3—Double-Layer Drum Winding

Then we have:

$$e = \frac{w^2\, l\, \lambda\, 2\, i_a\, v}{b}\ ;$$

the product $i_a\, w$, which represents the number of ampere turns in one armature coil, we may express as follows:

$$i_a\, w = \beta\, A\, S,$$

where β is the commutator pitch reduced to the periphery of the armature[2] and $A\,S$ is the linear load of the armature in amperes per cm. Comparing this expression with the preceding one, we have:

$$e = \frac{2\, w .\, v .\, \beta .\, A\, S .\, \lambda .\, l}{b}$$

inserting in this formula $b/\beta = n$ = number of commutator bars, short-circuited by the brush, we finally have:

$$e = 1/n \,.\, 2\, w \,.\, v \,.\; A\, S \,.\, \lambda \,.\, l \,. \qquad (1)$$

Chord-Drum Windings

With the drum armature type, which has two layers of winding, we must consider the mutual inductance of the conductors lying in the slot not only side by side, but also in the conductors lying one under the other in different layers.

Let e_1 = e. m. f. of self-induction generated in conductor 1 of the upper layer (A in Fig. 3).
e_2 = e. m. f. of self-induction generated in conductor 2 of the lower layer (B in Fig. 3).

The difference between the values e_1 and e_2 is caused by the difference in value of the slot-leakage coefficient for the conductors lying in the upper and the lower part of the slot; according to the tests made by the author, the mean ratio may be approximately $e_2/e_1 = 2.3$. In the case of double-layer drum winding, besides e_1 and e_2 the following e. m. fs. must be considered:

$k_{31}\, e_1$ = e. m. f. of mutual induction in conductor 1 of the upper layer generated by the alternation of the current in conductor 3 in the upper layer of the adjoining slot (Fig. 3).
$k_{21}\, e_2$ = e. m. f. in conductor 1 generated by conductor 2 in the lower layer.
$k_{41}\, e_2$ = e. m. f. in conductor 1 generated by conductor 4 in the lower layer.
$k_{42}\, e_2$ = e. m. f. in conductor 2 generated by conductor 4 in the lower layer.
$k_{12}\, e_1$ = e. m. f. in conductor 2 generated by conductor 1 in the upper layer.
$k_{32}\, e_1$ = e. m. f. in conductor 2 generated by conductor 3 in the upper layer.

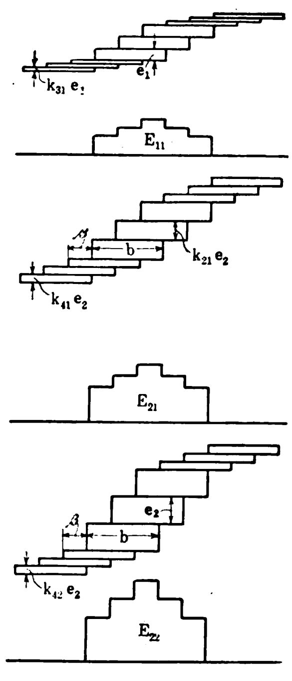

Fig. 4—E. M. Fs. Generated in Conductor of the Upper Layer (E_{11}, E_{21}) and E. M. Fs. in Conductor of the Lower Layer (E_{22}, E_{12})

In Fig. 4 is shown the graphical method of plotting the resulting e. m. f., when there are six conductors in one slot and the brush covers three commutator segments ($b = 3\,\beta$).

The staggered curve E_{11} represents the resulting e. m. f. curve in the conductor 1 of the *upper* layer generated by the conductors of the *upper* layer;

E_{21} represents the e. m. f. curve in the conductor 1

1. $b = b_k\, D/D_k$; where b_k is real width of the brush, D diameter of the armature and D_k diameter of the commutator.

2. $\beta = \beta_k\, D/D_k$, where β_k is real value of commutator pitch.

of the *upper* layer, generated by the conductors of the *lower* layer.

E_{22} represents the e. m. f. curve in the conductor 2 of the *lower* layer generated by the conductors of the *lower* layer.

E_{12} represents the e. m. f. curve in the conductor 2 of the *lower* layer generated by the conductors of the *upper* layer.

In case of full-pitch winding

(when $y_1 = K/p + 1$ and $K/2\,p$ = integer)

the curves E_{11}, E_{21}, E_{22} and E_{12} coincide in phase and the resulting e. m. f. induced in the short-circuited armature coil is the sum of the corresponding ordinates of the above-mentioned curves, as is shown in Fig. 5A.

When plotting Figs. 4, 5 and 6 the following values were taken for the e. m. f. coefficients:

$k_{21} = 0.70$; $k_{31} = 0.28$; $k_{41} = 0.28$;
$k_{12} = 1.20$; $k_{32} = 0.5$; $k_{42} = 0.30$; $e_2/e_1 = 2.30$;

These values were received from the test made by the author, and are described later on.

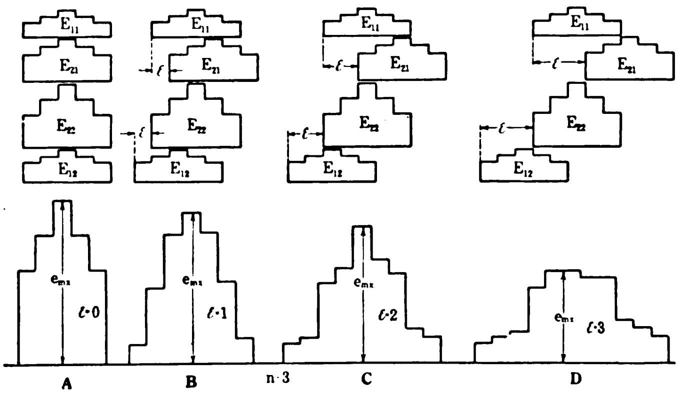

Fig. 5—Reactance Voltages (Resulting E. M. Fs.) Generated in Armature Coils of Chord-Drum Windings with Varied Shortening of the Pitch ϵ

Width of brush n = 3.

In case of drum short-pitch winding the curve E_{12} (see Fig. 5B) must be placed behind curve E_{11} at a distance of ϵ and curve E_{12} before E_{11} at the same distance ϵ, where

$$\epsilon = 1/2\,(K/p + 1 - y_1);$$

(K = number of commutator segments, p = number of pairs of poles, y_1 = first part-pitch of the winding.)

The above is explained by Fig. 6, from which it is seen that conductor 1 lying *over* conductor 2 of the armature coil K is short-circuited by the brush I ϵ commutator bars before the conductor 2, and conductor 2′, which lies in the slot under conductor 1′ is short-circuited on an equal number of commutator bars later than conductor 1′.

In Figs. 5A, B, C and D are shown the reactance voltage curves for ϵ = 0, 1, 2, 3 and $n = 3$[3], and in Fig. 7 the curves of the same values of ϵ but with lesser width of the brush ($n = 2$). From Figs. 5 and 7 it is seen that with the growth of ϵ (*i. e.* with increased shortening of the winding pitch) the maximum ordinate e_{mx} of the reactance voltage curve diminishes and that the value o this curve base correspondingly increases; from these figures it is seen also, that with the growth of ϵ the symmetry of e. m. f. curves is visibly reduced; this is not very desirable, because it requires the asymmetrical level of the interpole shoes.

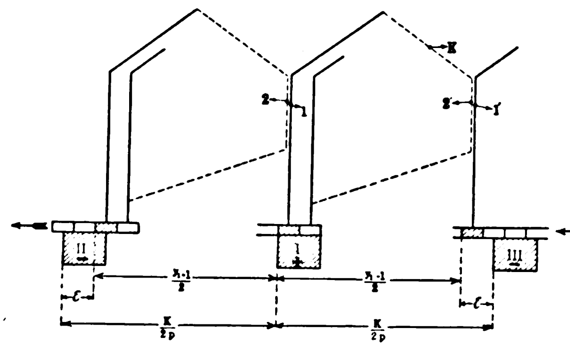

Fig. 6

From Figs. 4 and 5 we may see also the following fact, essential in theory of commutation: The reactance voltages induced in the *upper* and *lower* conductors of the armature coil have *not* an equal value; indeed we see, that the e. m. f. induced in the upper conductor 1 (see Figs. 6 and 4) is composed by adding the ordinates of E_{11} and E_{21} and the e. m. f. induced in the lower conductor 2′, by adding the curves E_{22} and E_{12}, and that the maximum ordinates of E_{22} and E_{12} are greater in the average than the maximum ordinates of the curves E_{21} and E_{11}.

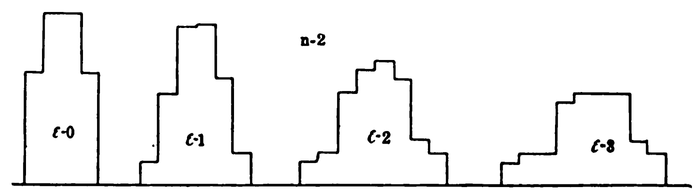

Fig. 7—Reactance Voltages Generated in Armature Coils of Chord-Drum Windings with Varied Shortening of the Pitch ϵ

Width of brush n = 2.

The ratio between these two resulting values of the reactance voltage, according to the author's tests with a 5-h. p. Lahmayer's motor is about 1.40. It is clearly seen that in machines with a double number of commutator segments[4] it is impossible to get an equally good commutation for all the armature coils by means of interpoles.

In machines with a normal number of commutator segments, the magnetic field of interpoles must be of such value, as to compensate *in average* the sum of reactance voltages of the upper and lower conductors of the short-circuited armature coil.

3. The resulting curve $E_{11} + E_{21}$ represents the e. m. f. generated in the upper conductor 1 of armature coil K; the curve $E_{22} + E_{12}$ represents the e. m. f. generated in the lower conductor 2′ of the same armature coil K (see Fig. 6).

4. *i. e.*, with one armature bar for one commutator segment.

In Fig. 8 is plotted the curve of e_{mx} as a function of the value ϵ for $n = 3$.

Full-Pitch Armature Windings

When the part pitch of winding y_1, the number of commutator segments K and the number of pairs of poles p correspond to the conditions of $y_1 = K/p + 1$ and $K/2\,p$ = *whole number*, then, in each conductor of the upper layer the commutation takes place simultaneously with that in the corresponding conductor of the lower layer, lying in the same slot. Therefore to simplify the question, we may suppose

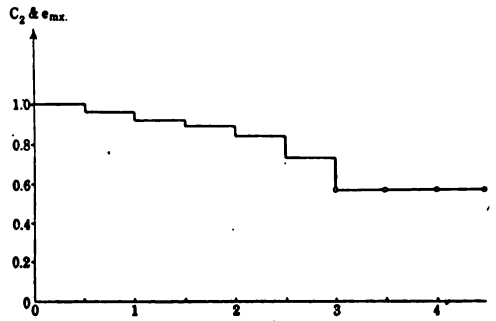

Fig. 8—Influence of Pitch Shortening ϵ upon Value of Reactance Voltage

that each of the upper conductors of the slot is joined with the corresponding lower conductor and instead of the slot a (Fig. 9) we may consider the slot b with half the number of conductors.

In Fig. 10 are shown several curves for the armature with six conductors in one slot (or three "joined" conductors).

In Fig. 10D, the rectangles 7, 8 and 9 represent the *e. m. f. curves of self-induction,* induced in conductors 7, 8 and 9 (Fig. 11). The *resulting* e. m. f. generated in one of the conductors in the slot III

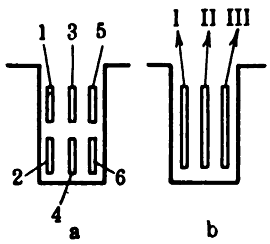

Fig. 9

(Fig. 11) will be greater than *e. m. f. of self-induction* due to mutual induction of other conductors lying in the same slot III and in the adjacent slots II, I and IV, V; the influence of the conductors in the adjacent slots can be found by plotting the rectangles with reduced ordinates $k_1\,e$ placed at a distance from each other equal to the width of commutator segment β (see rectangles 4, 5, 6, 10, 11, 12 in Fig. 10D). The influence of the conductors 1, 2, 3 and 13, 14, 15 (Fig. 11) in more distant slots can be found in the same way graphically, constructing the reactangles of e. m. fs. 1, 2, 3 and 13, 14, 15 (Fig. 10D) with reduced ordinates $k_2\,e$.

According to the author's tests, which will be described later on, in the average, k_1 equals 0.28 and $k_2 = 0.13$. Thus we get the curve of resulting e. m. f. *a b c d e f g h k l m* (Fig. 10D) induced in any conductor, when the latter, with the armature rotation, crosses the commutation zone.

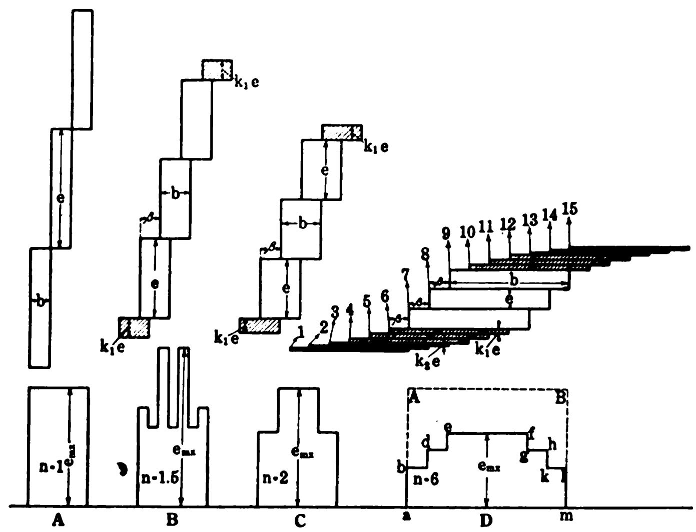

Fig. 10—Reactance Voltages Generated in Armature Coils of Full-Pitch Armature Windings

With various widths of brush.

($b/B = n = 1, n = 1.5, n = 2, n = 6$)

($n_t = 3$)

Let us try to find the expression for th maximum value of resulting e. m. f. e_{mx} (reactance voltage). Denoting the e. m. f. of self-induction by e we may write according to Fig. 10D:

$$e_{mx} = 3\,e + 3\,k_1\,e\,;$$

generally we may write:

$$e_{mx} = n_t\,e + (n - n_t)\,k_1\,e \qquad (2)$$

where $n = b/\beta$ = the number of commutator segments, covered by the brush, and n_t = the number of

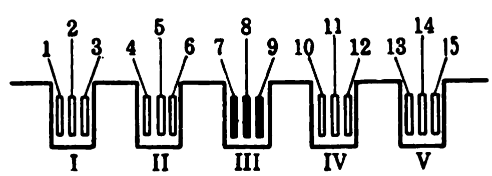

Fig. 11

commutator segments corresponding to one slot. Denoting $N = n - n_t$ we may rewrite this equation as follows:

$$e_{mx} = n_t\,e + N\,.\,k_1\,e = (n_t + N\,k_1)\,e \qquad \textbf{(2a)}$$

The formula (2) is correct only when $n > n_t$; if n is a fraction, the difference $(n - n_t)$ in the expression (2) must be raised to the next *integer*; when $n < n_t$ and n is a fraction, the maximum value of reactance voltage may be expressed by the following formula:

$$e_{mx} = N_1\,e \qquad \textbf{(2b)}$$

where N_1 is the next greater integer to n (when n is an integer, the value N_1 in the equation (2b) is taken as equal to n).

Putting in the equations (2a) and (2b) the expression for e from the equation (1) we find

$$e_{mx} = (n_t/n + N/n\,k_1)\,2\,w\,v\,A\,S\,.\,\lambda\,.\,l \tag{3}$$

and

$$e_{mx} = (N_1/n)\,2\,w\,v\,.\,A\,S\,.\,\lambda\,.\,l \tag{4}$$

Thus we may write

$$e_{mx} = C\,.\,2\,w\,.\,v\,.\,A\,S\,.\,\lambda\,.\,l \tag{5}$$

where $C = n_t/n + N/n\,k_1$ (6)
(when $n > n_t$)

and $C = N_1/n$ (7)
(when $n < n_t$)

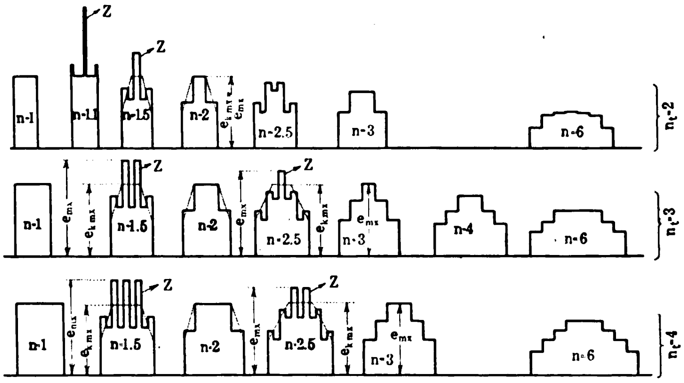

Fig. 12—Reactance Voltages Generated in Armature Coild of Full-Pitch Armature Windings

With various widths of brush (n) and varied number of commutator segments for one slot (n_t).

The formula (5) differs from the well-known formula of Prof. Pickelmayer[5] by the presence of the multiplier C.

In the ideal case of $k_1 = k_2 = 1$, (which never occurs in practise) that is when the coefficient of mutual-induction for conductors lying in different slots equals 1, the formulas (2a) and (5) become:

$$e_{mx} = n\,.\,e$$

and $e_{mx} = 2\,w\,.\,v\,.\,A\,S\,.\,\lambda\,.\,l$.

In this case, instead of the staggered curve of reactance voltage, we get the reactangular shape $a\ A\ B\ m$ in (Fig. 10 D), where the maximum and average values of reactance voltage coincide.

For this ideal case the coefficient C in the equation (5) becomes equal to 1 and the author's equation (5) becomes identical with the equation of Prof. Pichelmayer.

Pichelmayer's equation has been recently very much discussed in the technical literature[6]; the absence of the width of brush in Pichelmayer's formula raised the greatest criticism. One group of scientists (Pichelmayer and others) supposed that the mean value of reactance voltage does not depend practically on the number of commutator segments crossed by the brush and, that therefore it is quite possible to use Pichelmayer's formula, in which the width of brush is not given.

The other group, (Lamme, Niethammer and others) suppose that it is quite impossible to neglect the relation between the reactance voltage value and the width of the brush when calculating the interpoles.

As will be seen later on, both groups were right to a certain degree; the author of this article shows later on, that, when the width of the brush is small, when $n < n_t$, it is quite possible to use Pichelmayer's formula for calculating the interpoles; with brushes of a larger width, when $n > n_t$ it is necessary to put a correcting multiplier C in Pichelmayer's formula.

Reactance voltage curves for different cases ($n_t = 2, 3, 4$ and $n = 1, 2, 3 \ldots . 6$) have been plotted according to the above described method; in Fig. 12 is represented the result of such plotting; from this figure we see that with the increase of the brush-width (see formula 3) e_{mx} decreases; when $n < n_t$ sharp teeth Z appear in the reactance voltage curves, which badly affect the commutation; with the gradual diminution of the width of brush the height of these teeth Z increases and their width decreases, so that when the number of commutator segments covered by the brush is an integer, the tooth takes the limited shape of a straight line (compare for example the teeth Z for $n = 1.5$ and $n = 1.1$, when $n_t = 2$. in Fig. 12).

According to the above described graphical method e_{mx} as a function of the number of segments crossed by the brush $n = b/\beta$ is plotted in reactangular coordinates for $n_t = 2$, 3 and 4 (Fig. 13, 14, 15). From these figures it is seen that this function has the shape

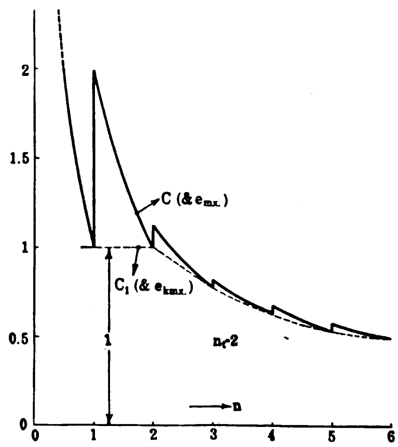

Fig. 13—Reactance Voltage e_{mx} (Solid Line) and Compensating Voltage Generated by the Interpoles e_{kmx} (Dotted Line) as a Funcion of the Brush Width n

Number of commutator segments for one slot $n_t = 2$.

of a toothed curve, approaching the axis of the abscissas with the rise of n; from Figs. 13-15 it is seen that when $n > n_t$ the teeth of the curves become smaller than when $n < n_t$.

Calculation of Interpoles

The interpoles must produce in the neutral zone a magnetic field of such a form and strength as to

5. See *Electrotechnische Zeitschrift*, 1912, p. 3.

6. See *Electrotechnische Zeitschrift*, 1912, pp. 3, 266, 524, 523, 602.

compensate the reactance voltage not only in its mean but also in its instantaneous value. As is seen from Fig. 12, the strict compensation of the reactance voltage is impossible, due to its staggered shape; it is especially difficult to carry out this compensation with the small number of segments crossed by the brush ($n < n_t$) when the teeth Z (Fig. 12) in the reactance voltage curves are strongly developed.

Although we may suppose that in reality the amplitude of this tooth voltage Z strongly diminishes, due

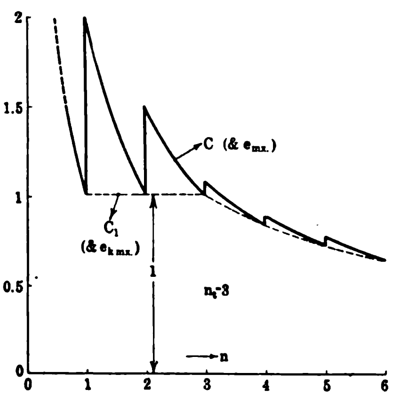

FIG. 14—e_{mx} AND e_{kmx} AS A FUNCTION OF n; $n_t = 3$

to eddy currents, which appear in the iron of the armature teeth and in the solid conductors, still we must in designing the machine try to diminish this tooth voltage.

From Fig. 12 it is seen that the small tooth voltage Z in the reactance voltage curves may be received, when brushes of large width are being used, not less than $n = n_t$; therefore it is necessary, if possible, to use brushes sufficiently wide in order to fulfil this condition($n > n_t$).

The fine lines on Fig. 12 represent the curves of the voltages, which must be generated by the interpoles for the approximate compensation of reactance voltage. The author finds that the maximum value of compensating voltage e_{kmx} may be determined with sufficient exactness for practise according to the equation

$$e_{kmx} = C_1 \,.\, 2\,w\,.\,v\,.\,A\,S\,.\,\lambda\,l \tag{8}$$

where $$C_1 = \frac{n_t}{n} + \frac{(n - n_t)}{n}\,k_1 \tag{8a}$$

(when $n > n_t$)

and $$C_1 = 1 \tag{8b}$$

(when $n < n_t$)

The expressions (**8a**) and (**8b**) must differ from the equations (6) and (7) in the following way: The difference $n - n_t$ must be taken *as it is* and *not* raised to an integer, as we have done in formulas **6** and **7**. The curves of the variation of coefficient C_1 and e_{kmx} in function of n are shown in Figs. 13-15 as dotted lines. In Fig. 12 are shown the e. m. fs. e_{kmx} received from the formula **8** (fine lines). The equations (7) and (8) are correct only for full-pitch windings; for short-pitch windings the equations (5) and (8) can be somewhat changed:

$$e_{mx} = C\,.\,C_2\,.\,2\,w\,v\,.\,A\,S\,.\,\lambda\,.\,l \tag{9}$$

$$e_{kmx} = C_1.\,C_2\,.\,2\,w\,v\,A\,S\,.\,\lambda\,.\,l \tag{10}$$

where the coefficients C and C_1 have their former meaning and the coefficient C_2 represents the result of the pitch shortening and may be found from Fig. 8; when the value of the pitch shortening does not exceed $\epsilon = 1/2$ on basis of Fig. 8 we may find $C_2 = 1$.

Examples: We will take for example the lap winding with $n_t = 3$ and

$$\epsilon = 1/2\,(K/p + 1 - y_1) = 1/4\,;$$

suppose also that for this winding

$$e_0 = 2\,w\,.\,v\,.\,A\,S\,.\,\lambda\,.\,l\,.\,10^{-8} = 1 \text{ volt};$$

when $n = 3.\,2$ commutator segments, we have

$$C = \frac{n_t}{n} + \frac{N}{n}\,k_1 = \frac{3}{3.2} + \frac{1}{3.2}\,0.28 = 1.03;$$

(the value k_1 according to the author's tests is taken as 0.28; N, the next greater integer to $n - n_t = 3.2-3$, is taken equal to 1).

We have

$$C_1 = \frac{n_t}{n} + \left(\frac{n - n_t}{n}\right) k_1 = \frac{3}{3.2} + \frac{3.2 - 3}{3.2} \times 0.28 = 0.96\,;$$

$$C_2 = 1\,;$$

$$e_{mx} = C\,.\,C_2.\,e_0 = 1.03 \times 1 \times 1 = 1.03 \text{ volts};$$

$$e_{kmx} = C_1.\,C_2.\,e_0 = 0.96 \times 1 \times 1 = 0.96 \text{ volt};$$

thus:

$$\frac{e_{kmx}}{e_{mx}} = \frac{0.96}{1.03} = 0.93\,;$$

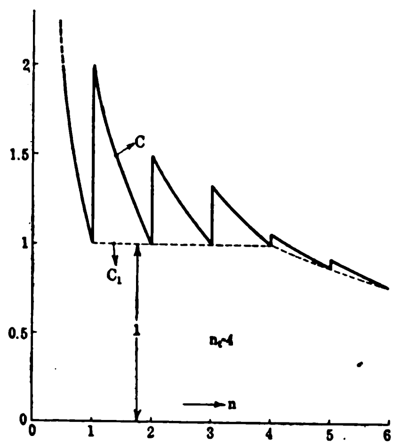

FIG. 15—e_{mx} AND e_{kmx} AS A FUNCTION OF n; $n_t = 4$

that is about 7 per cent of the maximum reactance voltage remains uncompensated. With $n = 2.2$ we get the following values for the coefficients:

$$C = \frac{N_1}{n} = \frac{3}{2.2} = 1.36$$

(N_1 is the next greater integer so $n = 2.2$, that is $N_1 = 3$);

$C_1 = 1$ according to the equation (**8b**);

$C_2 = 1$;

$$e_{mx} = C\,C_2\,e_0 = 1.36 \times 1 \times 1 = 1.36 \text{ volts};$$

$$e_{kmx} = C_1\,C_2\,e_0 = 1 \times 1 \times 1 = 1 \text{ volt};$$

We have: $\dfrac{e_{kmx}}{e_{mx}} = \dfrac{1}{1.36} = 0.73\,,$

that is about 27 per cent of the maximum reactance voltage remains uncompensated (see the teeth Z in Fig. 12).

The shape of the shoe of the interpole must be such as to enable, if possible, the reactance voltage compensation in every period of commutation. From the curves in Fig. 12 it is seen that with a small number of short-circuited segments ($n > n_t$) the best pole shoe is such as shown in Fig. 16, where $a = b$ and $\delta_1 = 2\,\delta$; with a greater number of short-circuited segments it is best to take $a > b$; for a more strict determination of the shape of the shoe it is better first to plot the curves of the reactance voltage and then to choose the shape of the interpole shoe.

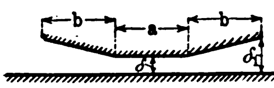

FIG. 16—SHOE OF THE INTERPOLE

EXPERIMENTAL DATA

The problem of finding experimentally the curve of reactance voltage, the author solved in the following way. The armature A of the test direct-current machine[7] was cut and the new ends of the armature winding were joined with the contact rings a and b as shown in Fig. 17; the current from these contact rings by means of the brushes and of conductors was led up to the *immovable armature coil* S placed in the slots of an *immovable* armature. The exploring wire O, lying together with the armature coil in the same slot of the armature (see also Fig. 3) was joined with the strip II of the oscillograph, thus enabling us to observe the curve of e. m. f. generated in this conductor by the variation of current in the armature coil S (the curve of reactance voltage).

The strip of the oscillograph I with the shunt N gave the oscillogram of current curve in the armature coil S.

The switch u and the battery B served for calibrating of the strip II.

The advantage of this method is, that we deal with an *immovable* and approachable armature coil, where all the commutation phenomena take place in the same way as if the coil formed a part of the winding of a *rotating* armature.

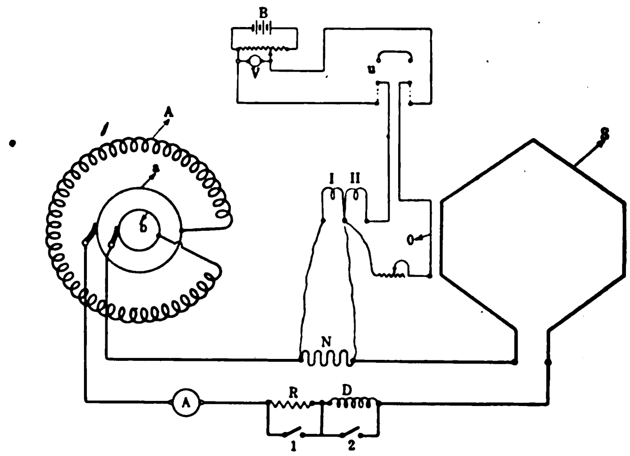

FIG. 17—EXPERIMENTAL SCHEME OF CONNECTIONS

The resistance R and the choke coil D could be connected to the circuit of the coil S by opening the corresponding switches 1 and 2, and enabled us to find the influence of additional resistance and additional self-induction in the short-circuited armature coil on the commutation phenomena.

THE REACTANCE VOLTAGE CURVES

In Figs. 18 to 26 are shown the oscillograms of reactance voltage and current in the armature coils.

In order to vary the current strength and the period

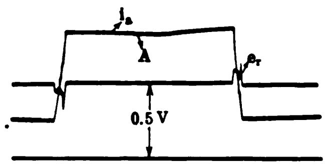

FIG. 18—OSCILLOGRAMS OF REACTANCE VOLTAGE e_r AND CURRENT i_a

i_a = 15 amperes.
n = 300 rev. per min.
Interpoles excited.

of commutation, the direct-current machine (the armature winding of this machine is denoted by A on Fig. 17) was started as a motor; the variations of speed of the motor and consequently the variations of the period of commutation were obtained by the variation of the excitation current of the machine; the variations of the current strength in the tested armature coil S were obtained by the torque variations on the shaft of this machine.

In the slots of the stationary armature were placed

7. The experiments were made with a "Lahmeyer" shunt-wound motor, of which he following are the specifications:

Horse power	5
Terminal voltage	100 volts
Current	5 amperes
Speed rev. per min	200/1200
Number of poles	4
Armature:	
Diameter	312 mm.
Length	750 mm.
Air gap	2 mm.
Commutator:	
Diameter	245 mm.
Number of segments	207
Number of brush spindles	4
Number of brushes per spindle	2 (10 × 20) mm.
Armature Winding:	
Series drum winding in	69 slots
Number of conductors per slot	12
Number of armature conductors	828
Commutating Poles:	
Width of pole	22 mm.
Length of pole	110 mm.
Winding	68 turns per pole

the armature coils; the exploring conductor O (Fig. 17) was placed in the slot at half the height of them (see also Fig. 3. In all tests the length of the exploring conductor was equal to the length of the stationary armature. The dimensions of the stationary (ton wound) armature are the following: Diameter, 250 mm.; length, 110 mm.; number of slots, 40; slot dimensions, 10 × 26. The tested armature coils had

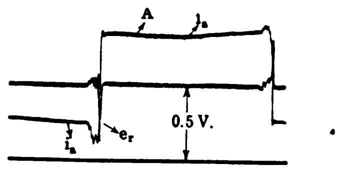

FIG. 19—OSCILLOGRAMS OF REACTANCE VOLTAGE e_r AND CURRENT IN ARMATURE COIL i_a
i_a = 15 amperes.
n = 300 rev. per min.
Interpoles not excited.

three turns in series; the diameter of the conductors was 2.5 mm. In order to damp the natural vibration of the oscillograph strip castor oil was used.

In Fig. 18 is shown the current curve i_a in the armature coil and the reactance voltage curve e_r, the speed of the motor being $n = 300$ rev. per min., and the strength of current $i_a = 15$ amperes (the interpoles were excited).

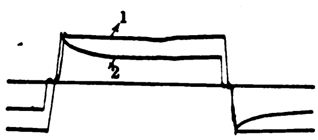

FIG. 20—CURRENT OSCILLOGRAMS WITH THE ADDITIONAL RESISTANCE (2) AND WITHOUT IT (1)

In Fig. 19 are shown the curves taken at the same current $i_a = 15$ amperes and at the same speed, $n = 300$ rev. per min., but with the interpoles not excited; comparing Figs. 18 and 19 we see that with the interpoles not excited the shape of the reactance voltage curve changes strongly and the maximum value of reactance voltage rises from 0.16 volt to 0.41 volt, *i. e.*, 2.56 times.

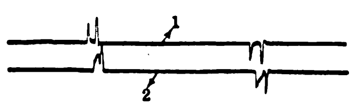

FIG. 21—REACTANCE VOLTAGE GENERATED IN ARMATURE COIL WITH THE ADDITIONAL RESISTANCE (1) AND WITHOUT IT (2)

In Fig. 18 is seen the saddle-shape curve of reactance voltage. This shape may be explained by two causes: By a great ohmic resistance of the tested armature coil, and by non-coincidence in the shape of the e. m. f. curve, generated by the interpoles, and the reactance voltage curve; the first supposition is confirmed by Fig. 21 and the second by Fig. 22.

In Fig. 21 are shown two oscillograms: Below, the oscillogram of reactance voltage for the tested armature coil; and above, in the oscillogram of the reactance voltage in the same armature coil but with the introduction of additional resistance $R = 1.2$ ohms (Fig. 17). As is seen from the oscillograms, with the presence of the additional resistance R the saddle-shape of the reactance voltage curve is more projected.

In Fig. 20 are shown the current oscillograms with the resistance R and without it, (1, the curve without R; and 2, the current curve with $R = 1.2$ ohms).

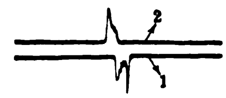

FIG. 22—REACTANCE VOLTAGE
1—Brushes on the neutral zone.
2—Brushes displaced relatively to the neutral.

The curve lineal shape of the line 2 (Fig. 20) may be explained in the following manner: At the rotation of the armature with an additional resistance R in an armature coil the ohmic resistance of each armature circuit in parallel will vary periodically, depending on the presence or absence of R in the corresponding circuit; due to such variation of the ohmic resistance the strength of the current in each parallel circuit must vary; the variation of current due to a great self-

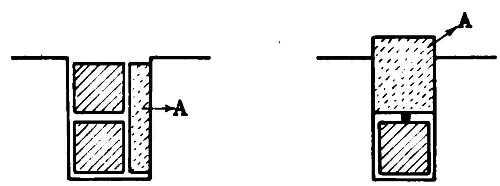

FIG. 23 AND 24—ARMATURE SLOTS WITH SOLID COPPER IDLE CONDUCTORS A

induction of the armature winding cannot take place suddenly, but proceeds according to the exponential curve 2 on Fig. 20. In Fig. 22 are shown two oscillograms: Below, the oscillogram of reactance voltage when the brushes are on the neutral zone; and above, when the brushes are displaced relatively to the neutral on five commutator segments against the direction of armature rotation; as is seen from the upper curve

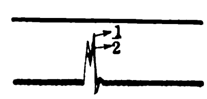

FIG. 25

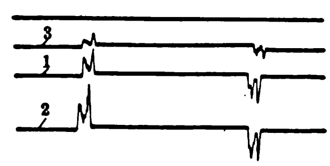

FIG. 26

the saddle-shape character of the reactance voltage curves is lost.

In order to decrease the teeth of the reactance voltage curves (Fig. 12) and in general to decrease the value of the reactance voltage itself, when the conditions of commutation are heavy, it is possible to put in the armature slots besides the conductors of the armature windings the *idle conductors* of solid copper, A (Fig. 23)

in which, when crossing the commutating zone, must develop eddy currents, which produce a damping effect on the slot flux and decrease the reactance voltage. In order to verify this last supposition the following test was made: Into the slot of the stationary armature was put a solid copper conductor A (area of section, 9×14 mm.) due to which the value of the reactance voltage had been decreased 25 per cent (see Fig. 24). Fig. 25 shows the oscillograms of this test (1, the curve of the reactance voltage at normal conditions; 2, the reactance voltage curve, when a solid copper idle conductor was put into the slot.

THE TRANSFORMATION RATIO OF THE ADJACENT ARMATURE COILS

The exploring wires I, II, III and IV were put into the slots, as was shown in Fig. 3. The armature coil fed by the armature current was placed in the slot in the position B (Fig. 3). In Fig. 26 are shown the corresponding oscillograms taken when $i_a = 15$ amperes and $n = 300$ rev. per min.; according to these oscillograms the following relations between the maximum values of the e. m. fs. generated in the conductors I, II, III were obtained:

$$e_2 : e_1 : e_3 = 14.5 : 10 : 4.1.$$

In the same manner the relations were obtained between the e. m. fs. generated in the exploring wires with the armature coil placed in the position A (see Fig. 3). According to these tests the values of the coefficients were obtained, as given before.

CONCLUSION

In conclusion we may give the following summary:

1. The maximum value of reactance voltage e_{mx} decreases with the growth of the width of the brush b; this relation between e_{mx} and b does not represent a continuous function but is represented by a toothed curve, like that in Figs. 13, 14 and 15.

The maximum value of e. m. f. generated by the interpoles with a small number of segments crossed by the brush ($n < n_t$) does not depend on the width of the brush, but with $n > n_t$ must decrease with the growth of the brush width (see formula **8**).

2. With strongly shortened pitch of the armature windings we get the asymmetrical curve of reactance voltage e_{mx}, therefore it is necessary to avoid such windings; with small shortening of the pitch its influence on the value and the shape of e_{mx} is not very important (see Fig. 8).

3. In order to get a smooth curve e_{mx} without sharp teeth it is necessary to design machines with a great number of slots and few commutator segments n_t for each slot.

We must adhere to the following rule when calculating the width of the brush: *The number of segments n crossed by the brush must be, if possible, not less than the number of commutator segments for one slot n_t.* Following the last rule we get a reactance voltage curve of smooth shape, and consequently an almost full compensation of reactance voltage by the interpoles may be obtained.

WORLD-WIDE ACTIVITY IN STEAM RAILWAY ELECTRIFICATION

Due apparently to the marked increase in price of fuel which has taken place during the past few years, steam railroads all over the world are studying the possibilities of electrification as a means of lowering operating expenses.

Most of the leading countries in Europe have announced plans either to increase the present mileage of electrified steam railways or to carry out such work where hitherto electrification was not regarded as economically feasible. In South America, Brazil and Chile either have work under construction or are about to let contracts for such projects.

In Asia, Japan and India are both making investigations with a view to electrifying certain suburban or heavy-traffic sections. In Australia the suburban lines out of Melbourne have been in process of electrification for some years, and other projects in that country are under discussion. In Africa the question of electrifying steam railways of the Union of South Africa has reached the stage where bids have been invited and are in the hands of the consulting engineers, who are expected before long to place some part of the initial construction contract.

In the past, whenever the question of electrification has been taken up, the matter of increasing the capacity of a section of steam railway has probably been the greater factor, rather than reduction in operating expenses. Now the high price of coal throughout the world has brought the latter factor into the greater prominence.

It is interesting to note that in many of the larger countries abroad the heavy trunk-line electrification projects in the United States have been very carefully studied and are very frequently referred to by foreign consulting engineers in their reports, and that in several instances standard American plans have been adopted practically complete by engineers advising foreign governments on steam railway electrification. It is believed that the experience of American manufacturers in developing reliable heavy railroad equipment in this country will be of considerable help in negotiating a foreign contract.—*Commerce Reports.*

A license has been issued to the Alaskan-American Paper Corporation for a hydroelectric development at Orchard Lake, Revillagigedo Island, Alaska. The installation of 5200-horse power hydraulic turbines is contemplated, the power to be used in the operation of a pulp and paper mill. The elevation of Orchard Lake will be raised 32 feet by a rock-fill dam at its outlet from which water will be conducted through a wood-pipe conduit 2000 feet to the power house. All pulp-wood grinding machines will be directly connected to hydraulic turbines, and all other machinery and appliances in the mill will be electrically driven.

Physical Conceptions of Induction Motor Operation

BY J. LEBOVICI

Designing Engineer, Triumph Electric Company

CONFRONTED by the particular behavior of the single-phase induction motor, it is but natural that in order to familiarize ourselves with it, we should substitute for the direct, the indirect description, and explain the single-phase motor by means of the better known polyphase performance. This indirect method originated by E. Arnold and F. Eichberg and recently modified by B. G. Lamme, looks upon the single-phase induction motor as a special case of the polyphase motor and considers it as a revolving field machine.

Yet in the same manner as it has been found advisable to abandon today the indirect method of describing heat phenomena by means of Black's heat substance, for the direct description through the more general principles of modern energetics, it may be preferable to abandon the explanation of the single-phase motor performance by the polyphase for a more direct method. Of the direct methods, the one originated by Potier

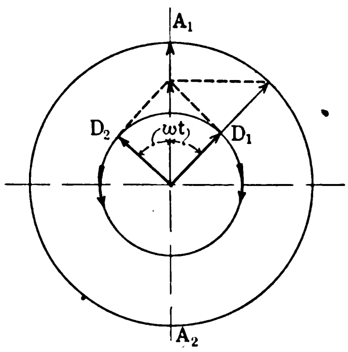

Fig. 1

and G rges and further developed by V. Fynn, McAllister and others, carefully studies the action of the secondary rotating member in the production of a field at right angles in space and time phase to the transformer field.

Since the right angle field is generally called the speed field or cross flux, we can refer to the direct method as the "cross-flux theory" and to the indirect method as the "revolving-field theory."

It is known that the circular current locus or circle diagram determines the performance of the induction motor with an accuracy well within the limits of the practical engineer's needs. The circle diagram is determined when the following three characteristic points are given: The no-load or synchronous speed current, the locked or short-circuit current and the infinite speed current points. Based on either the revolving-field theory or the cross-flux theory analytical expressions for the three characteristic current values can be obtained. It has been shown by E. Arnold that the characteristic current values are the same when calculated from the formula obtained by either method.

V. Karapetoff has shown that the two equivalent diagrams of a single-phase induction motor can be converted into each other, or in other words that the two theories lead to the same performance of a motor with given design constants.[1]

It follows that both methods, when carefully handled lead to the same current locus and, in consequence, to the same motor performance.

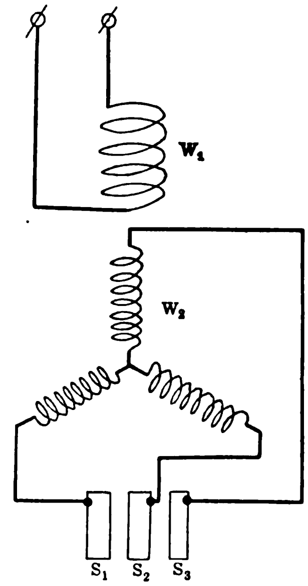

Fig. 2

The revolving-field theory requires more expert handling and is apt to lead to results at variance with experiment unless very carefully interpreted. An instance of such misinterpretation is given below.

The revolving-field theory assumes that a single phase alternating magnetic field $O A$ (see Fig. 1) may be considered as made up of two fields $O D_1 = O D_2 =$

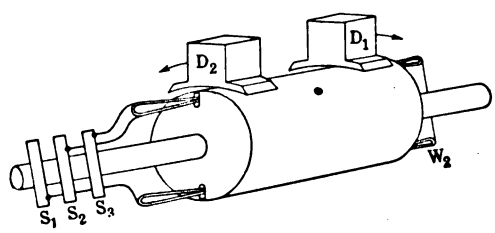

Fig. 3

$\frac{1}{2} O A_1$ of constant value and rotating at uniform speed in opposite directions.

Consider on the basis of this theory, the e. m. fs. generated in the secondary of the slip-ring motor shown in Fig. 2, the primary winding W_1 being connected to a single-phase line and the secondary W_2 being stationary and open circuited. For the sake of

1. See August 1921 Journal of the American Institute of Electrical Engineers, page 640.

better visualization, Fig. 3 has been drawn, showing the rotor core of sufficient length to accommodate the two oppositely revolving fields D_1 and D_2 of constant value. Applying the knowledge obtained from a familiarity with polyphase induction motors to the field D_1 we might expect that it would generate a system of balanced voltages in the secondary winding W_2. Similarly the revolving flux D_2 would produce a system

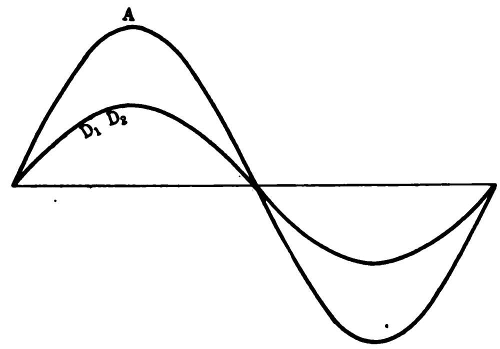

Fig. 4

of balanced voltages in the same windings, W_2. As resultant, we might expect a balanced voltage between slip rings S_1, S_2 and S_3 or otherwise zero voltage.

Experiment as well as unbiased consideration of Fig. 2 will prove that the secondary voltages are neither zero nor balanced and that the effective voltages measured between slip rings S_1, S_2 and S_3 are dependent upon the relative position of the rotor with relation to the stator.

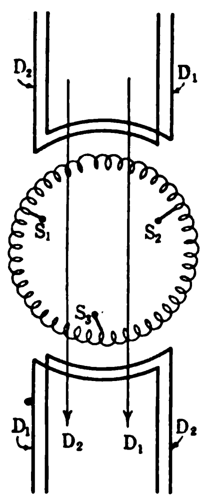

Fig. 5

The discrepancy is due to improper application of the revolving field theory and also shows the defect of the indirect method.

At the instant shown in Fig. 4 and Fig. 5 the magnetic flux A, set up by the primary winding W_1, is at its maximum value. According to Fig. 1, the two component fields D_1 and D_2 each of half a value will coincide both in space (see Fig. 5) and time (see Fig. 4) value. Since in Fig. 5 at the instant considered the fields D_1 and D_2 are both positive with respect to the rotor winding W_2 and rotating in opposite direction the instantaneous value of the e. m. fs. generated in W_2 will be zero.

A quarter of a period later the value of the flux A has decreased to zero and according to Fig. 1, the rotating fields D_1 and D_2 will have the time and space values shown in Figs. 6 and 7. If D_1 is considered positive with respect to the rotor windings W_2 the field D_2 will have to be considered negative. As field D_1 is positive and traveling clockwise while the field D_2 is negative and traveling counter clockwise the e. m. fs. generated in the windings W_2 will add up along a vertical axis in Fig. 7. It is evident from

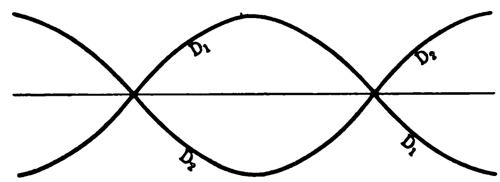

Fig. 6

Fig. 7 that the generated e. m. fs. add between slip rings S_1-S_3 and S_2-S_3 but oppose each other between slip rings S_1 and S_2. This explains why the effective voltages measured between slip rings S_1, S_2 and S_3 under the assumed conditions will be unbalanced.

Proceeding by the direct method we would look upon Fig. 2 as a static transformer, having the secondary open circuited, and since the various secondary phases are not in the same inductive relation with respect to the primary winding we would naturally expect unbalanced secondary voltages.

In deriving the induction motor performance (polyphase and single-phase motors alike) by means of the

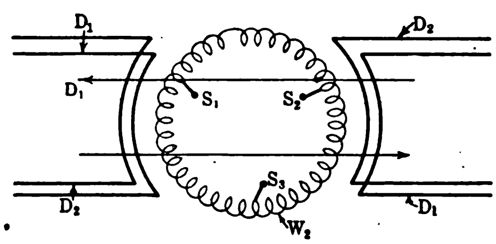

Fig. 7

revolving-field theory, we lost track of the important part played by the secondary leakage in the motor performance. The action of the secondary leakage in improving the power factor of all induction motors is not appreciated and the means for improving the power factor of induction motors by the use of phase advancers or the substitution of a commuted secondary winding for the short-circuited rotor windings are not apparent. On the other hand when proceeding by the cross-flux theory, these phenomena are quite evident. This is one reason why the action of the polyphase induction motors (and of single-phase induction motors without and with commutators)

should be studied by the direct method rather than in a roundabout way by means of the rotating-field theory.

The only reason for deriving the single-phase motor performance from the polyphase instead of going back to fundamental laws as is done by the adherents of the cross-flux theory is the belief that the underlying polyphase motor principles are so well understood. On the other hand it may be pointed out that before the polyphase induction motor is well understood a familiarity with the principles of the static transformer action as well as of the direct-current motor action is necessary. Taking further into consideration that the revolving-field theory is abandoned when we begin to deal with the single-phase commutator motor and that the operation of any type of motor can be derived from fundamental principles without recourse to the revolving-field theory, it would seem logical to derive the polyphase motor performance from fundamental principles without the use of the revolving-field theory.

Considering that science in general and applied science have as a goal a greater economy of thought, it follows that of the two theories, the direct method covering a greater field of phenomena should be given preference in all cases.

From a scientific as well as pedagogical point of view the writer believes that the direct method should be used in deriving the polyphase and single-phase motor performance and obviate the necessity of describing the polyphase motor by the indirect method, then modify this method to suit the single phase induction motor and abandon it when we come to investigate the single-phase commutation motor.[2]

PLANT ADDITIONS BY SOUTHERN CALIFORNIA EDISON COMPANY

During the past year, the Southern California Edison Company has made at three points additions to its hydroelectric plant system totaling 92,000 horse power. These additions consist in Kern River number three plant rated at 40,000 horse power, a new 22,000-horse power generator in Big Creek number two plant, and Big Creek number eight plant rated at 30,000 horse power. According to the Edison Company, the completion of Big Creek number eight plant will remove all possibility of a power shortage this fall during the period when plants without storage are operating at reduced output due to low stream flow. The plant, which is located on the San Joaquin River at its junction with Big Creek, was put into operation on August 12, construction work on the building and in the installation of apparatus normally requiring one year having been completed within three and one-half months. This is the first plant constructed on the Edison System and will probably be the first plant in the world to be put into operation utilizing transmission electrical pressure as high as 220,000 volts. The Edison Company in conjunction with Professor Ryan of Leland Stanford University has been carrying on extensive experiments with the purpose of perfecting its plans to convert the present Big Creek line from an operating electrical pressure of 150,000 volts to 220,000 volts. It is probable that operation at the higher voltage will be accomplished during next year. In the meantime energy from Big Creek number eight plant will be transmitted at 150,000 volts. Transformer equipment for the power house was purchased so that it would be possible to operate temporarily at 150,000 volts, and later on with the conversion of the Big Creek line to the higher electrical pressure to deliver the output from this plant at 220,000 volts. Increasing the voltage on the Big Creek lines from 150,000 to 220,000 volts will double their capacity to transmit energy at a cost much below the duplication of another set of 150,000-volt transmission lines. Economy in transmission costs is the end to be accomplished by the conversion of the present Big Creek lines to the higher operating voltages.

The California Railroad Commission has authorized the Southern California Edison Company to construct an additional plant in the Big Creek hydroelectric development, to be known as Big Creek power house number three. One hundred fifty thousand kilowatts capacity is planned for this power house. Two generating units of approximately 25,000 kilowatts each will first be installed.

A forebay reservoir will be created by a diversion dam on the main San Joaquin River, diverting the waters to the power house intake through a tunnel 23 feet in diameter and approximately six miles in length. The ultimate supply will be 500,000 acre-feet, at approximately 7000 feet elevation and 825 feet total effective head at the turbines. This enormous supply of water available for power purposes throughout the entire year will come from the combined capacity of Huntington Lake, Shaver Lake, the main San Joaquin River and a system of reservoirs to be constructed for conserving and delivering the waters of several smaller sources.

One million barrels of fuel oil, the consumption of steam plants necessary to produce the equivalent amount of electrical energy, will be saved by an output from this power house of 204,000,000 kilowatt-hours of electricity during 1923. Less than five mills per kilowatt-hour is the estimated cost of production of electric current by the initial development. This cost will be reduced by the ultimate development to slightly in excess of two mills, as compared with an average cost of seven mills per kilowatt-hour for steam-generated current.

The first unit is planned for completion in April, 1923, and the second unit in July of the same year. An expenditure of $11,500,000 will be required up to that time. The cost of the complete development is placed at $17,500,000.

2. The application of the direct method to various types of motors has been shown in a series of articles entitled "Power and Torque in Electric Motors" published in *The Electrical Review* Chicago, dated Jan. 4, 1919 and subsequent numbers.

Use of the Tangent Chart for Solving Transmission Line Problems

BY RAYMOND S. BROWN

Columbus, Ind.

Introduction

THE general problem of finding the steady-state electrical conditions at some point of a transmission line when they are known at some other point has been a fascinating one for writers, and many schemes, most of them giving approximate solutions, have been proposed for lessening the labor of solving such problems. Dr. A. E. Kennelly has shown that the exact solution of such problems is most simply given by the use of hyperbolic functions and he has been a pioneer in the application of these functions to transmission line problems. About five years ago the writer devised a method, based on hyperbolic functions, for obtaining the exact solution, by applying them in such a manner that the use of tables is unnecessary, provided a special diagram, called a tangent chart, is available. The chart is entirely general in its application, not depending on any particular frequency or length of line. It was described in an article in French, prepared by Messrs. Marius Latour and Geo. Viard from notes furnished them by Dr. C. O. Mailloux, which was published in *La Revue Générale de l'Electricité*, July 20, 1918. The very favorable consideration which the method received in Europe, and the demand for the publication of a description of the method in the English language, led the writer to take up its study anew, recently, with the idea of improving it, and extending its applicability and practical usefulness. The result is the present paper, which contains an entirely new presentation of the method, in its latest and most complete form.

General Considerations

In any system of conductors for the transmission of electric power, the dielectric plays just as important a role as does the conductor itself. The dielectric, or shunt, constants, conductance and electrostatic capacity, are always present, even though their effects may be insignificant when compared with those of the series constants, resistance and inductance. It is only when the shunt effects are intensified by high voltage, high frequency, or the use of some dielectric other than air, that we must take the shunt constants into account in the solution of transmission line problems. If a line possessed series constants only, or shunt constants only, the fact that these constants were uniformly distributed over the length of line, would have no significance, and problems involving such a line could be solved by the simple application of Ohm's law. Where, however, both kinds of constants are taken into account, their distributed nature must be recognized to get the true solution. Ohm's law can then be applied to a differential length of line, only. The result is, that the expressions for current and voltage, as obtained by integration, are hyperbolic functions of the length of line. In the case of alternating-current transmission, all quantities involved are complex numbers or vectors. In the case of power lines, whose length embraces only a small part of the length of a wave, approximate solutions are frequently used, based upon the expansion of these functions into series. Such approximations do not require the use of tables and give results quite close enough for many purposes provided harmonic frequencies do not need to be taken into account. In the case of telephone lines the length of line embraces an appreciable part of the length of a wave, due to the higher frequency, and approximate solutions are practically never allowable.

In place of the algebraic solution, the writer proposes the use of a chart which will show graphically the electrical conditions at any cross-section of a transmission line operating in the steady state. This graphical method applies to lines having uniformly distributed shunt and series constants and embraces both power and telephone lines of any length, voltage, frequency, or type of construction.

The solution by chart is both simpler and quicker than the algebraic solution, even where approximate equations are used, and it offers the additional advantage that it presents to the eye a picture of the *exact* electrical condition at *every* point of the line. It lessens the chance for numerical error and aids greatly in studying the operation of a line, as the effect produced by a change in load or line constants is shown almost at a glance, without the necessity for working through a lot of tedious mathematics. One of the greatest advantages, however, of this method is that is enables the quantity, watts, or *effective power* at any point of the line, to be represented geometrically by the location of a point in a plane, so that the power may be read directly, without reference to current or voltage, by the mere projection of this point onto a suitable scale.

In order to understand the theory of this chart a working knowledge of the hyperbolic functions of complex numbers is essential. However, just as a slide rule may be used effectively by one who does not understand logarithms, this chart may be used by those not familiar with hyperbolic functions after they understand the method of procedure. The chart is, in fact, a transmission line slide rule, and its use is similar in many respects to that of the ordinary slide rule. Since it deals with complex numbers in place of scalars it is necessary, however, to construct it in two dimensions in place of one.

Vector Expression

There are two methods in general use for expressing the numerical value of a vector or general number; the rectangular form such as $4 + j\,3$, where $j = \sqrt{-1}$, and the polar form, $5\,\sigma^{j36.8°}$ or, as it is more conveniently written, $5 \underline{/36.8°}$. In problems involving sums and differences, only, the rectangular form is more convenient to handle, and in problems involving products and ratios only, the polar form is preferable. The method of solution presented here involves products and ratios almost exclusively, so all quantities are expressed in the polar form.

Line Constants

Let l = the length of the transmission line in miles.

$z = r + j\,x$ = the impedance per mile of conductor.

$y = g + j\,b$ = the admittance per mile of dielectric.

I and E the vector current and voltage respectively, measured to the neutral plane.

$N = \sqrt{z/y}$, a constant usually called the natural impedance, surge impedance, or characteristic impedance of the line. It is defined as the sending end impedance of an infinite length of transmission line having the same cross-section as the actual line. Its dimension is resistance, ohms.

$a = \sqrt{z\,y}$, is called the propagation constant of the line. Its dimension is L^{-1}. The real component of the propagation constant is called the attenuation constant, since it influences the attenuation of current and voltage per mile. The imaginary component is called the wave length constant, since it influences the phase rotation of current and voltage per mile of line.

$A = a\,l$, is called the complex angle subtended by the line. It is a numeric. The real component is called the attenuation of the line and the imaginary component, the wave length of the line.

The solution of problems relating to the line involves hyperbolic functions of the attenuation, which is thus expressed as a number, and circular functions of the wave length, which may thus be expressed in radians or degrees.

The constants N and a depend upon and replace, in the following analysis, the elementary constants, z and y, which are used in approximate solutions. The elementary constants can usually be found tabulated in electrical handbooks. The constants N and a, so far as the writer knows, have never been tabulated and must be computed from z and y. A table of N and a for various sizes and spacings of open wire would be a valuable addition to the modern handbook as these are the constants used in all exact solutions of transmission line problems.

Fundamental Equations

The differential equations applying to an element $d\,l$ of a transmission line, l being measured from the receiving end, are,

$$\frac{d\,E}{d\,l} = z\,I \qquad\qquad \frac{d\,I}{d\,l} = y\,E$$

The solution of these equations gives,

$$E = E_o \cosh A + N\,I_o \sinh A \tag{1}$$

$$I = I_o \cosh A + E_o/N \sinh A \tag{2}$$

The subscript zero denoting receiving end quantities.

These are the equations ordinarily used for the exact solution. Since they contain both sums and products of vectors they are not well adapted to computation using either the polar or the rectangular form of vector expression. A much more convenient form and one well adapted to solution by chart is obtained as follows:

Let, $$W = \tanh^{-1} E/N\,I \tag{3}$$

$$W_o = \tanh^{-1} E_o/N\,I_o \tag{4}$$

Then,

$$E/E_o = \cosh A + \coth W_o \sinh A$$

$$I/I_o = \cosh A + \tanh W_o \sinh A$$

$$\frac{E}{E_o} = \frac{\sinh (W_o + A)}{\sinh W_o}$$

$$\frac{I}{I_o} = \frac{\cosh (W_o + A)}{\cosh W_o}$$

Let, $$W = W_o + A \tag{5}$$

Whence,

$$E \propto \sinh W \tag{6}$$

$$I \propto \cosh W \tag{7}$$

Voltage and current at any point of a transmission line are thus shown to be proportional, respectively, to the hyperbolic sine and cosine of a complex angle, W, whose hyperbolic tangent is the ratio of total impedance to natural impedance. Furthermore, the angle W increases uniformly by the amount a for every mile of line passed over.[1]

These equations are well adapted to the polar form of expression, the vector addition $W = W_o + A$ being performed graphically by the use of the chart.

The Tangent Graph

The terminus of the complex angle W may be located in a plane corresponding to any known value of the ratio $E/N\,I$. The simplest manner in which to locate this point is to construct a graph or Argand diagram of the function, $\tanh W = \tanh (u + j\,v)$. Such a chart is shown in Fig. 1.

Let $$\tanh W = E/N\,I = T = t \underline{/\phi}$$

t will represent the magnitude or modulus of T and ϕ will represent its direction or argument.

The curves marked with angles in Fig. 1 were plotted by assigning successive constant values to ϕ while t was varied, and the curves marked with numbers were plotted by assigning successive constant values to t while ϕ was varied. The scalar equations from which these two families of curves were plotted were obtained as follows.

---

1. The fact that E and I may be expressed as simple hyperbolic sine and consine functions of a complex angle is shown by Dr. A. E. Kennelly in his book "Hyperbolic Functions Applied to Electrical Engineering."

From the vector equation,

$$t\,(\cos\phi + j\sin\phi) = \tanh\,(u + j\,v)$$
$$= \frac{\tanh u + j\tan v}{1 + j\tanh u\tan v}$$

GRAPH OF TANH (u + jv)
s Scale

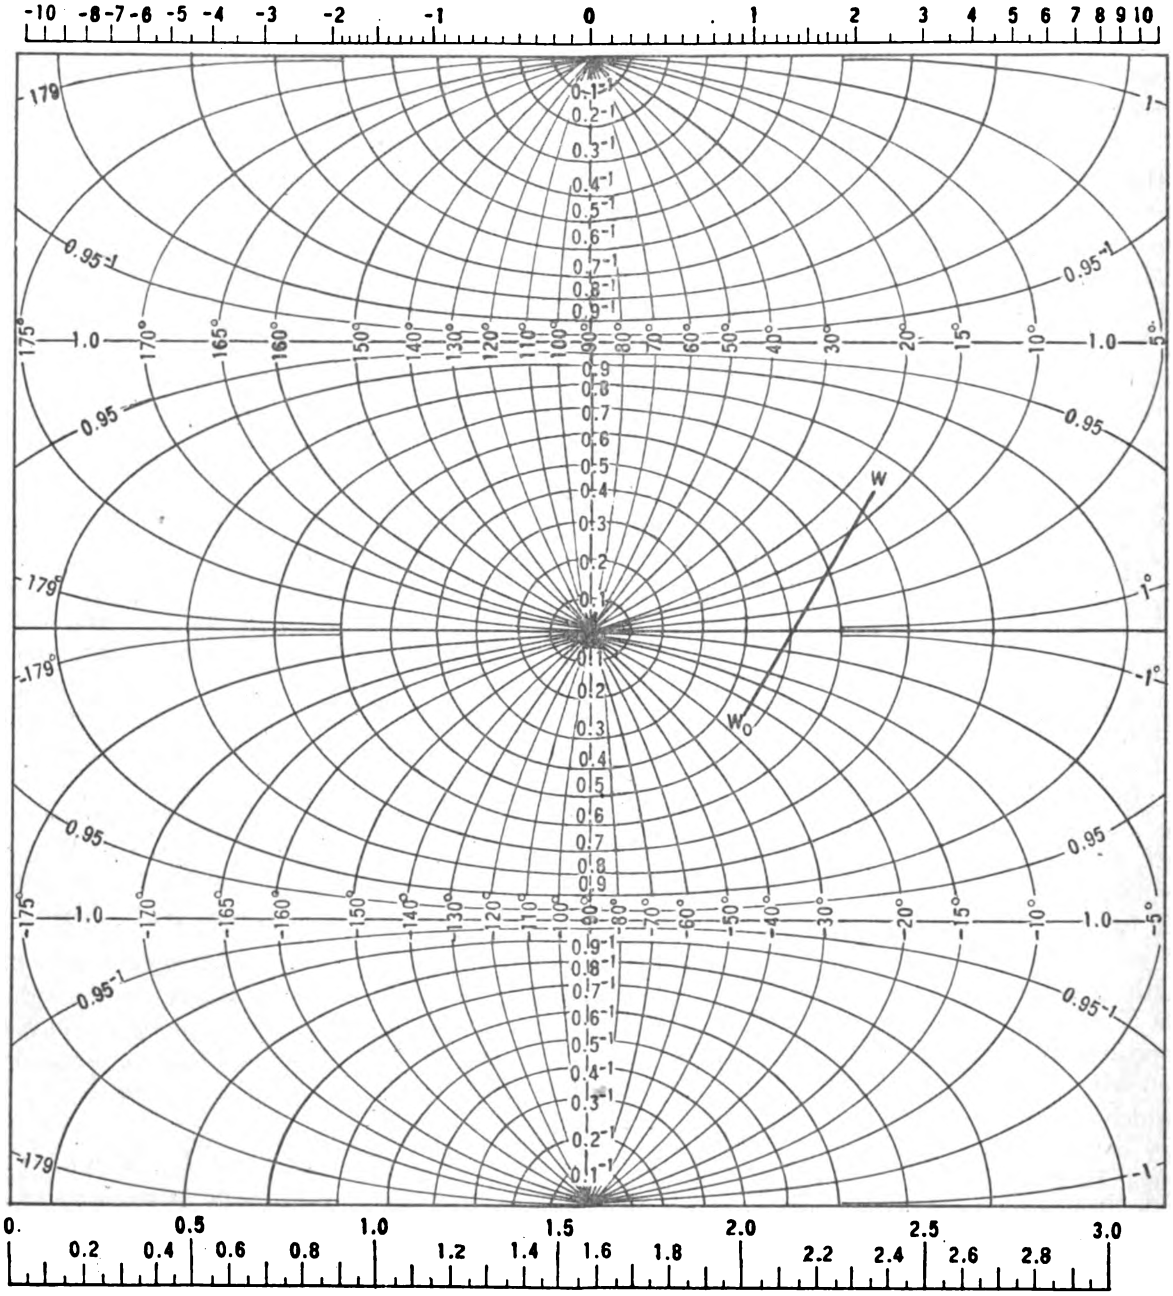

FIG. 1

we get the two scalar equations,

$$\frac{\sin 2\,v}{\sinh 2\,u} = \tan\phi \qquad (8)$$

$$\frac{\cos 2\,v}{\cosh 2\,u} = \frac{1 - t^2}{1 + t^2} \qquad (9)$$

as the equations of these curves.

It will be noted that the two families are orthogonal, which tends to make easy the location of points at their intersection.

The tanh W function is periodic in the direction of the V axis, repeating in the interval $j\,\pi$. It is non-periodic in the direction of the U axis. The graph may thus be thought of as the surface of a cylinder, of diameter equal to unity, which for convenience has been cut parallel to the U axis and spread out into a plane.

Since the circular and hyperbolic tangents bear the relation $\tan W = -j\tanh j\,W$, the graph of tanh W, Fig. 1, becomes also the graph of tan W if the chart is rotated 90 deg. and the numbers on each of the angle

curves reduced by 90 deg. The tan W function is thus periodic in the direction of the real axis and non-periodic in the direction of the imaginary axis.

If we compute the numerical value of the ratio $E/N\,I$ in the polar form we can readily locate the point W by the use of this chart. Supposing known conditions to be at the receiving end of the line, we designate the corresponding value of W by W_o. If we add graphically to W_o the vector $A = a\,l$, by laying it off from the point W_o we arrive at the point W since by equation 5, $W = W_o + A$. The value of $t \underline{/\phi}$ read from the curves at the point W gives us the ratio $E/N\,I$ at the sending end of the line. The angle A being directly proportional to length of transmission line, enables us, should we so desire, easily to find the ratio T, at any intermediate point on the transmission line. Multiplying T by N gives us the sending end impedance E/I at the point W.

Should the point W fall at the center of Fig. 1 it indicates the condition $E/N\,I = 0$ or the corresponding point on the transmission line is grounded, $E = 0$. Should W fall at the other focus of the chart it indicates the condition $N\,I/E = 0$ or the corresponding point on the transmission line is free, $I = 0$.

The region beyond the right and left hand boundaries of Fig. 1 indicates $T = 1$ or the sending end impedance at every point is equal to the natural impedance. This condition exists when the load is of such a character that waves of current and voltage sent out by the generator suffer no terminal reflection. When W travels in this region the phase relation between I and E remains constant and, as W recedes from the V axis both I and E increase in the ratio, σ^a for every mile of line passed over.

The tangent chart illustrates very well the so called Ferranti effect, such as is exhibited by long power lines when operating under light load. In this condition the line acts somewhat like a transformer and converts from low voltage and large current at the sending end to high voltage and small current at the receiving end. An inspection of Fig. 1 shows this effect to be most pronounced when the length of transmission line is a quarter wave length, $A = j\,\frac{1}{2}\,\pi$, as A is then just long enough to span from the $E = 0$ focus to the $I = 0$ focus. The condition $A = j\,\frac{1}{2}\,\pi$ is never fully attained in practise due to dissipation of power in the conductor and dielectric, consequently the vector A always has a real component.

Voltage and Current

We have seen that the tangent chart enables us to find the value of total impedance at any point of the transmission line. We shall now show how voltage and current may be obtained at this point.

Let, $H = \sinh 2\,W = 2 \sinh W \cosh W$

Whence, $H \propto E\,I$ and, since $T \propto E/I$

$$E \propto \sqrt{H\,T} \qquad I \propto \sqrt{H/T}$$

H is given in terms of T by the hyperbolic relation,

$$H = \frac{2\,T}{1 - T^2}$$

Having found from the chart the values of T at any two points on the transmission line, and knowing the values of E and I at one of these points, we can thus find, by simple proportion, the values of E and I at the other point. E and I thus determined are vector quantities, the phase angles of which are measured with respect to the voltage (or current) at some arbitrary point, for instance, the receiving end of the line.

In the great majority of problems we are not interested in the phase of E and I, individually, but only in their relative phase, as it is the angle included between these two vectors which determines the power factor. This relative phase is fully determined by the ratio, T, as found from the chart. We are, however, interested in the individual *scalar* values of E and I. It is possible to find these scalar values much more easily than by the use of the above equation for H, as this equation involves both sums and ratios of vectors and is, therefore, not well adapted to computation.

Let, e = the scalar value of E

i = the scalar value of I

h = the scalar value of H

Then,

$$e \propto \sqrt{h\,t} \qquad i \propto \sqrt{h/t}$$

$$\frac{1}{2\,H} = \frac{1}{T} - T = \frac{1}{t}(\cos\phi - j\sin\phi) - t(\cos\phi + j\sin\phi)$$

$$h = \frac{1}{\sqrt{1/4\,(t + 1/t)^2 - \cos^2\phi}} \qquad \textbf{(10)}$$

We can then find the scalar values of E and I at any point on the line by means of the proportions,

$$\frac{e}{e_o} = \sqrt{\frac{h\,t}{h_o\,t_o}} \qquad \textbf{(11)}$$

$$\frac{i}{i_o} = \sqrt{\frac{h\,t_o}{h_o\,t}} \qquad \textbf{(12)}$$

These are scalar equations and well adapted to computation.

Should the point W fall at the $E = 0$ focus of the chart, we have by equation (10)

$$t = 0 \quad h = 0 \quad \sqrt{h\,t} = 0 \qquad \sqrt{h/t} = \sqrt{2}$$

and should it fall at the $I = 0$ focus we have,

$$1/t = 0 \quad h = 0 \quad \sqrt{h\,t} = \sqrt{2} \quad \sqrt{h/t} = 0$$

In place of obtaining h from equation **10** it may be found more easily by expressing it in terms of u and ϕ thus,

$$H = \sinh 2\,W = \sinh 2\,u \cos 2\,v + j \cosh 2\,u \sin 2\,v$$

$$h = \sinh^2 2\,u + \sin^2 2\,v$$

Eliminating v by means of equation **8**,

$$h = \frac{\sinh 2\,u}{\cos\phi} = \frac{s}{\cos\phi} \qquad \textbf{(13)}$$

The use of this equation requires an additional scale, that of $s = \sinh 2u$, which is shown at the top of the chart. This scale also serves another useful purpose as will be shown later. It is read by projecting vertically from the point W.[2]

Equation **13** becomes indeterminate for all points on the V axis, $u = 0, \phi = \pm 90$ deg., and equation **10** must be used in its stead for such points.

Power Relations

If δ represents the argument of vector N and β the argument of vector I, E being taken as standard phase or zero argument,

$$t \underline{/\phi} = E/N\,I \qquad \phi = -\delta - \beta$$

Let p be the effective power or watts, then,

$$p \propto h \cos \beta = \frac{\sinh 2u}{\cos \phi} \cos(\phi + \delta)$$

$$= \sinh 2u\,(1 - \tan \delta \tan \phi) \cos \delta$$

$\cos \delta$ being a constant, may be dropped from the proportion. Eliminating ϕ by means of equation 8,

$$p \propto \sinh 2u - \tan \delta \sin 2v$$

The power will be zero when

$$\frac{\sin 2v}{\sinh 2u} = \cot \delta = \tan(\pm \pi/2 - \delta)$$

This is the equation of that particular angle curve on the chart, Fig. 1, for which $\phi = \pm \pi/2 - \delta$ or $\beta = \pm \pi/2$

But $\beta = \pm \pi/2$ implies that current and voltage are in quadrature. Hence all points on this particular angle curve represent the condition of zero power factor and this curve may thus be designated the zero power factor wave.

This wave makes the angle δ with the V axis at the origin. Similarly we have a unity power factor wave

$$\frac{\sin 2v}{\sinh 2u} = \tan - \delta \text{ making the angle } \delta \text{ with the } U$$

axis at the origin.

Denoting the abscissa of the zero power factor wave by u' we get,

$$p \propto \sinh 2u - \sinh 2u'$$

$$p \propto s - s' \qquad (14)$$

The result of this analysis is shown graphically in Fig. 2 where the zero power factor wave is shown for one and a half cycles. In this particular case δ is a negative angle.

The inclined straight line represents the locus of the point W. This line, if sufficiently extended, will cut the zero power factor curve in one point and only one. This corresponds to a point on the transmission line at which the power factor is zero but neither current nor voltage is zero. In other words, power is flowing toward this point from both directions, as would be the case with a transmission line fed with power from two generating stations. The dotted line represents the locus of the unity power factor wave, $\phi = -\delta$. This curve will, in general, be intersected in more than one point, each intersection corresponding to the condition of unity power factor on the transmission line.

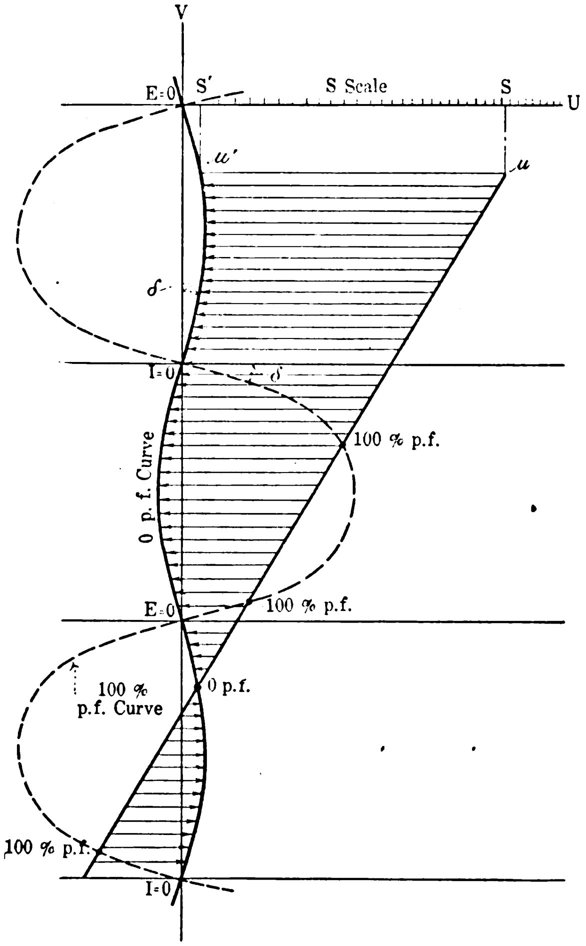

Fig. 2

Since $\sinh 2u$ always increases as u increases, the intercepted horizontal distance, shown shaded on the chart, may be considered as a rough measure of the power at any point.

The exact watt efficiency of any transmission line is given by,

$$f = \frac{s_o - s_o'}{s - s'} \qquad (15)$$

When N, A, and the load impedance are known the

2. If it were possible, without confusion of lines, to superpose on the tangent chart a graph of sinh W or cosh W, in which modulus curves only, were shown, each curve being marked with the parameter used in plotting it, we should have a means of finding the scalar values of E and I without the use of the s scale. This follows from equations **6** and **7**.

The tangent chart, as originally published, under the name of "Transmission Line Coordinate Paper," used this method, the modulus curves being drawn on the back of the chart and read by holding the chart up to transmitted light. It is believed that the present method is simpler, and in addition it permits the chart to be reproduced on an opaque surface.

The article by Messrs. Latour and Viard referred to in the introduction, contains a good description of the tangent chart, its mathematical basis and derivation and the practical use of the original form of tangent chart devised by the writer.

efficiency of any line may thus be very simply found, entirely without reference to current or voltage.

The maximum possible variation of δ is from -45 deg. to $+45$ deg. Thus s' can never be greater than unity, as represented by the projection of the crest of the wave.

Power flow is represented on the chart as always being *toward* the zero power factor wave. The receiving end of any A line which may be drawn on the chart will thus be whichever end of the A line is nearest this curve. Since ϕ usually lies between -90 deg. and $+90$ deg. the point W usually falls on the right side of the V axis and the left end of the A line is thus ordinarily the receiving end.

Maximum Efficiency

We have seen that for every position of the A line in the plane of the chart the corresponding watt efficiency of the transmission line may be readily found by the use of the zero power factor wave and the s scale. As the position of the A line recedes from the V axis the imaginary component of A, or the wave length of the transmission line, has less and less effect on the efficiency, until, when A reaches the region where $T = 1$, the efficiency approaches the constant value,

$$f = \left. \frac{\sinh 2\,(u + c)}{\sinh 2\,u} \right|_{u = \infty} = \sigma^{2c},$$

c being the attenuation. The efficiency, σ^{2c}, is however, the maximum efficiency only in the special case where $\delta = 0$, or the ratio $x/r = b/g$. This of course, includes the case of direct current where both x and b are zero. In all other cases the perturbing effect of the zero power factor wave is such as to produce an efficiency somewhat higher than σ^{2c} at a certain location in the plane. In order to find this particular location it is necessary to vary the position of A with respect to the U and V axes independently and solve the resulting equations simultaneously. This is accomplished as follows.

The efficiency pertaining to any location of the A line is,

$$f = \frac{\sinh 2\,u_o - \tan\delta \sin 2\,v_o}{\sinh 2\,u - \tan\delta \sin 2\,v}$$

u, v being the coordinates of the sending end and u_o, v_o of the receiving end.

Since f is to be a maximum with respect to both u and v,

$$\frac{\partial f}{\partial u} = 0 \qquad \text{and} \qquad \frac{\partial f}{\partial v} = 0$$

whence,

$$(\sinh 2\,u - \tan\delta \sin 2\,v) \cosh 2\,u_o\, \partial u_o = (\sinh 2\,u_o - \tan\delta \sin 2\,v_o) \cosh 2\,u\, \partial u$$

$$(\sinh 2\,u - \tan\delta \sin 2\,v) \cos 2\,v_o\, \partial v_o = (\sinh 2\,u_o - \tan\delta \sin 2\,v_o) \cos 2\,v\, \partial v$$

But, since u and u_o differ by a constant and v and v_o differ by a constant, $\partial u_o = \partial u$ and $\partial v_o = \partial v$

Whence, $f = \dfrac{\cosh 2\,u_o}{\cosh 2\,u}$ and $f = \dfrac{\cos 2\,v_o}{\cos 2\,v}$

Hence, $$\frac{\cos 2\,v_o}{\cosh 2\,u_o} = \frac{\cos 2\,v}{\cosh 2\,u}$$

$$\frac{1 - t_o^2}{1 + t_o^2} = \frac{1 - t^2}{1 + t^2} \quad \text{or} \quad t_o = t$$

Also, $$\frac{\sinh 2\,u_o - \tan\delta \sin 2\,v_o}{\sinh 2\,u - \tan\delta \sin 2\,v} = \frac{\cosh 2\,u_o}{\cosh 2\,u}$$

Replacing u and v by ϕ and t, by the use of equation **8** and **9** and using the relation found above, $t_o = t$,

$$\frac{1 - \tan\delta \tan\phi_o}{1 - \tan\delta \tan\phi} = \frac{\cos\phi}{\cos\phi_o}$$

$$\cos\delta \cos\phi_o - \sin\delta \sin\phi_o = \cos\phi - \sin\delta \sin\phi$$

$$\cos(\delta + \phi_o) = \cos(\delta + \phi)$$

$$\delta + \phi_o = \pm(\delta + \phi)$$

Ignoring the plus sign which gives $W = W_o$ we have,

$$\delta + \phi_o = -\delta - \phi$$

$$\phi_o + \phi = -2\,\delta \qquad \text{or} \qquad \beta_o = -\beta$$

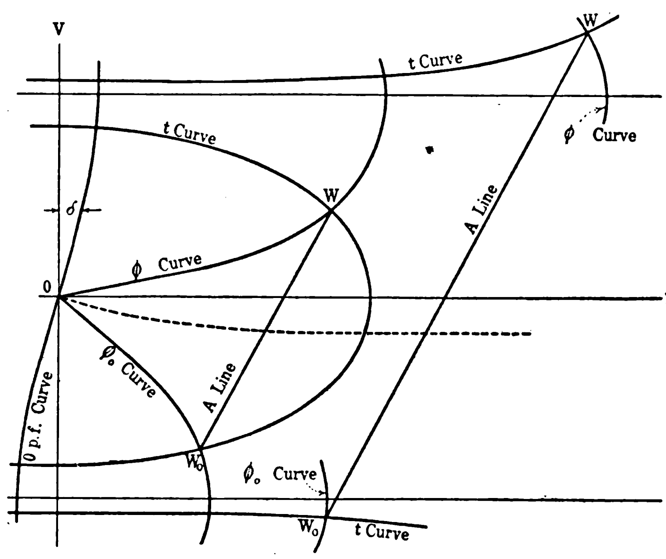

Fig. 3

The result of this analysis may be stated as follows. Any transmission line will operate at its maximum efficiency when the impedances at the opposite ends of the line are symmetrical. That is, the scalar values of the impedances and also the power factors must be equal at the opposite ends of the line but the current must lead the voltage at one end by the same angle that it lags at the other.

The location of the A line on the chart to attain this maximum efficiency may be found by the use of the ϕ, t curves and entirely without numerical computation. This is accomplished as follows, see Fig. 3.

Having laid the A line off along the edge of a strip of paper, move it slowly toward the V axis, being careful to preserve the proper slope and to keep the extremities, W and W_o, of the A line, on the same t curve at any position. The midpoint of the A line will move along a locus represented by the dotted line. Note the algebraic sum of $\phi + \phi_o$ as A approaches the V axis.

When this sum reaches the value $-2\,\delta$, the position of maximum efficiency will have been reached.

Since δ is the argument of the vector $\sqrt{z/y}$,

$$2\,\delta = \tan^{-1} x/r - \tan^{-1} b/g$$

Hence when b/g is greater than x/r, $2\,\delta$ is negative and $\phi + \phi_o$ is positive. The point O, Fig. 3, then represents the $I = 0$ focus of the chart, Fig. 1, because in this region ϕ_o is positive and numerically greater than ϕ.

When b/g is less than x/r, $\phi + \phi_o$ is negative and O represents the $E = 0$ focus.

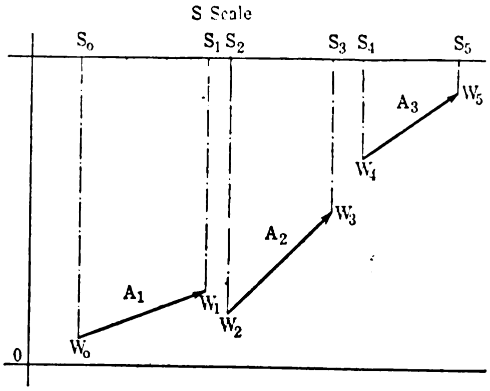

FIG. 4

The construction at the right of Fig. 3 shows the location of A when the length of transmission line is greater than a quarter wave length.

In the case of power lines having no leakage, the A line, for maximum efficiency, lies with its mid-point very near to the $I = 0$ focus. The load current is lagging nearly 90 deg. and the sending end current leading nearly 90 deg. This condition is only attained in practise on light, highly inductive load, such as transformer charging current. At full load the average power line works at somewhat less than maximum efficiency.

Composite Lines

The tangent chart may be used to good advantage for the solution of problems relating to composite transmission lines, that is to say, lines made up of sections in series having different constants, as for example, open wire and cable.

In general the locus of the point W for such a line will be a series of disconnected straight lines, each being the A line for that particular section, see Fig. 4. W_2 is found from W_1 by means of the relation,

$$T_2/T_1 = N_1/N_2$$

N_1 and N_2 being the natural impedances of the sections. I and E are the same on both sides of any junction.

The volt-ampere equation for such a composite line takes the form,

$$\frac{e_5\, i_5}{e_o\, i_o} = \frac{h_1 h_3 h_5}{h_o h_2 h_4}$$

Having thus found T and $e\,i$ at the distant end of the line, current and voltage are completely determined. The various A lines will alter their relative positions in the plane with change of load. Their individual lengths and slopes will remain constant however.

In the special case where the natural impedances of the various sections of line are all the same, the W locus becomes a continuous, broken line, and the line A, Fig. 5, representing the sum of the sections, may be used in their place. It is interesting to note that the terminal load is equivalent in its effect to an imaginary section of line, of the same natural impedance as that of the sections and whose value of A is W_o. The distant end of this imaginary section may be conceived as either grounded or free, depending upon whether the point O is the $E = 0$ or the $I = 0$ focus of the chart.

Series Loads

The solution for irregularly loaded telephone lines may readily be found by the use of the chart. The loads may be either series or shunt.

In the case of series loading, the terminal impedance being known, W_o is determined, Fig. 4. From this point lay off the vector A_1, corresponding to the first section of uniform line. This brings us to the first load at which we obtain the sending end impedance $E_1/I_1 = N_1\,T_1$ on the receiver side of the load. The impedance on the sending side of the load is $(N_1\,T_1 + Z)$ where Z is the impedance of the load. Hence,

$$T_2 = \frac{(N_1\,T_1 + Z)}{N_2}$$

and the point W_2 is determined.

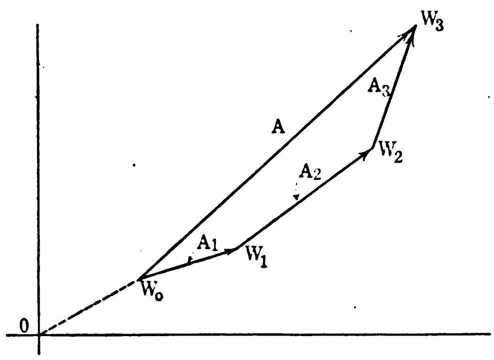

FIG. 5

From W_2 we proceed with the next uniform section of line and so on until all loads and all sections have been passed and we arrive at the final sending end impedance. The addition of impedances may be performed graphically on a separate sheet if desired.

The efficiency of such a loaded line is the product of the efficiencies of all the loads and all the sections. The efficiency of any uniform section of line is given by equation **15**. The efficiency of any series load is,

$$f_s = 1 - \frac{\text{loss}}{\text{input}} = 1 - \frac{r\, i_2^2}{e_2\, i_2 \cos\beta_2}$$

$$= 1 - \frac{r}{t_2\, n_2 \cos\beta_2}$$

where r is the resistance of the load, t_2, n_2, β_2 are measured on the sending side of the load and n_2 is the scalar value of N_2.

Shunt Loading

Lines containing shunt loads are solved in a similar manner except that the admittance is found at the sending end of each load and added vectorially to the admittance of the load. The corresponding formula for T_2 then becomes, $1/T_2 = N_2(1/N_1 T_1 + Y)$, Y being the admittance of the load. The formula for efficiency of a load becomes,

$$f_p = 1 - \frac{\text{loss}}{\text{input}} = 1 - \frac{g\, e_2^2}{e_2\, i_2 \cos \beta_2}$$

$$= 1 - \frac{t_2\, n_2\, g}{\cos \beta_2}$$

where g is the conductance of the load.

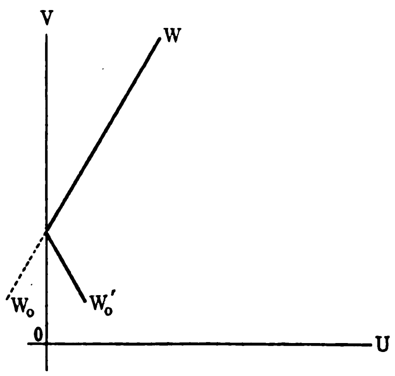

Fig. 6

This same method of solution may be applied to power lines having loads of known admittance tapped off at intervals, except that in this case the efficiency of the loads does not enter as a factor in the total line efficiency.

Direct-Current Lines

In the case of direct-current transmission lines such as cables, having distributed leakage and resistance, the constants N and A become real numbers and the A line lies in the U axis of the chart. The formulas for h, and e and i become,

$$h = s \qquad e \propto \sqrt{s\,t} \qquad i \propto \sqrt{s/t}$$

The similarity in principle between the tangent chart and the ordinary slide rule is quite evident in the case of direct current as both the tangent scale and the A scale consist of real numbers and are capable of being used on slides in the same manner as are the usual logarithmic scales.

The Work Chart

In using the tangent chart for numerical computation it is desirable, for reasons of accuracy, that it be drawn to as large a scale as possible. An inspection of Fig. 1 shows that, so far as the shape of the curves is concerned, regardless of the numbers attached to them, the diagram is symmetrical about the V axis and repeats itself at intervals of a quarter wave length, $\frac{1}{2}\pi$, along the V axis. This fact is taken advantage of in the construction of the work chart, which is an enlarged reproduction of the right central portion of Fig. 1. The curves are plotted to a scale twice as large as would be possible if the entire function were shown.

On the work chart, values of T greater than unity cannot be plotted. Due, however, to the relation,

$$\coth W = \tanh (W \pm j\, \tfrac{1}{2}\pi)$$

we may invert T whenever it is greater than unity, plot the resulting angle, and carry out the solution just as though we were working on the missing half of the chart. Our final result will then be read as $1/T$ or $N\,I/E$, which is the value of $\coth W$.

The left half of the tangent diagram has been omitted from the work chart for the reason that in most practical problems W will lie to the right of the V axis. In case, however, the A line should cross the V axis, it may be shown as reflected from the axis, as in Fig. 6. The value of ϕ as read at W'_0 will then be the supplement of the actual value at W_0. The value of t is the same at both points.

In case the A line runs off the top or bottom boundary of the chart it reappears at the opposite side and continues in the same direction as before, such that if the chart were rolled into a cylinder, parallel to the U axis, the A line would form a helix, see Fig. 7. In this case the A line is broken into two or more parts, as, A_1, A_2, A_3. If points on the line A_1 read the ratio $E/N\,I$ then points on A_2 will read $N\,I/E$, the ratio, T, inverting every time W passes off one boundary and reappears at the other.

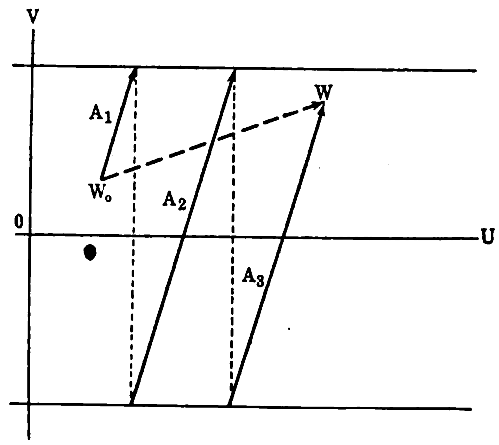

Fig. 7

For very long lines, an effective value of A_e, may be substituted for A. This is a fictitious value of A which will produce the same terminal effects as the actual value. When this substitution is made care must be taken to note whether W_0 and W read the same or inverse ratios of T.

It will be noted that the curves on the work chart are symmetrical about the U axis. This permits a chart of the top half, only, of the work chart to be used

if desired. Such a chart would be only one eighth of a wave length in height and would permit even a larger scale to be used, with a corresponding increase in accuracy. The locus of the point W on such a chart would appear as in Fig. 8. The sign of the angle ϕ would reverse with every reflection from the bottom boundary and the ratio T would invert with every reflection from the top boundary. The point W would follow the same path as would a billiard ball if rolled on a table, the cushions of which represent the boundaries of the chart.

Use of the Work Chart

The work chart, as here presented, may be used for the solution of transmission line problems without drawing upon it if a small triangle, representing the vector, A, be cut out of cardboard and laid upon the chart with its base parallel to the U axis. It may be

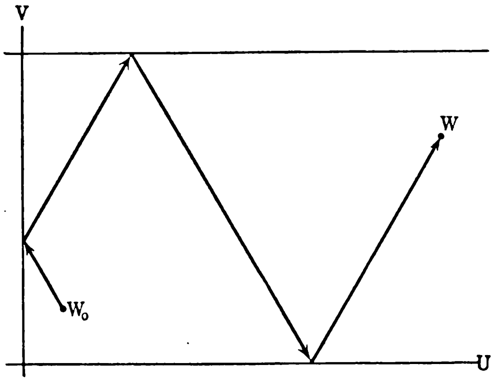

Fig. 8

moved about to represent various electrical conditions on the transmission line and the values of T_0 and T read off at the corners. In place of using cardboard, A may be drawn on a piece of tracing cloth and moved about over the chart. When using the work chart it is desirable to have it attached to a drawing board so that the s scale may be read by projection. The angle α has a possible variation of 90 deg. each way from zero but in most practical problems will be found to lie between 80 and 90 deg.

Numerical Example

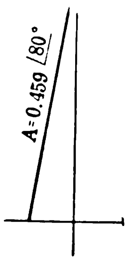
A three-phase power line has the following constants per wire,

$$Z = 60 + j\,165 = 175.5\,/\underline{70^\circ} \text{ ohms}$$

$$Y = 0 + j\,0.0012 = 0.0012\,/\underline{90^\circ} \text{ mhos}$$

Whence, $$N = \sqrt{Z/Y} = 382.5\,/\underline{-10^\circ} \text{ ohms}$$

$$A = \sqrt{Z\,Y} = 0.459\,/\underline{80^\circ}$$



If the voltage to neutral at the load is 60,000 volts and the load current is $90\,/\underline{-20^\circ}$ amperes, find the conditions at the sending end.

Solution

$$\frac{1}{T_o} = \frac{N\,I_o}{E_o} = \frac{382.5\,/\underline{-10^\circ} \times 90\,/\underline{-20^\circ}}{60000} = 0.574\,/\underline{-30^\circ}$$

T_o being greater than unity, the inverse ratio must be used. Plotting the value $1/T_o$ we read $s_o = 1.115$ whence,

$$h_o = \frac{s_o}{\cos\phi_o} = \frac{1.115}{\cos -30^\circ} = 1.288$$

Laying off vector A from the point W_o, we reach W, from which we read the conditions at the sending end,

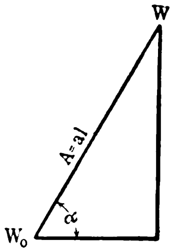


Fig. 9

$$\frac{1}{T} = \frac{N\,I}{E} = .516\,/\,8^\circ$$

$$h = \frac{s}{\cos\phi} = \frac{1.36}{\cos 8^\circ} = 1.373$$

Hence the phase of sending end current with respect to sending end voltage is $\beta = 8 - \delta = 18^\circ$ lead.

The scalar values of sending end voltage and current are found by the use of equations **11** and **12** to be,

$$e = e_o\sqrt{\frac{h\,t}{h_o\,t_o}} = 60{,}000\sqrt{\frac{1.373 \times 0.574}{1.288 \times 0.516}} = 65{,}300 \text{ volts.}$$

$$i = i_o\sqrt{\frac{h\,t_o}{h_o\,t}} = 90\sqrt{\frac{1.373 \times 0.516}{1.288 \times 0.574}} = 88.2 \text{ amperes, scalar value.}$$

The efficiency of transmission is,

$$f = \frac{h_o \cos\beta_o}{h\cos\beta} = \frac{1.288 \times \cos -20^\circ}{1.373 \times \cos 18^\circ} = 92.8 \text{ per cent.}$$

The efficiency may also be found without reference to E or I by equation **15**,

$$f = \frac{s_o - s_o'}{s - s'} = \frac{1.115 + 0.115}{1.36 - 0.035} = 92.8 \text{ per cent.}$$

The zero power factor curve in this case is the 80° wave, since current and voltage are in quadrature at all points on this curve, $\beta = 80^\circ + 10^\circ$.

If we wish to find the sending end voltage and charging current of the above line at no-load, we lay off the A line from the origin $1/T_o = 0$, and read the value of $1/T$ and s at the upper end of the A line, whence,

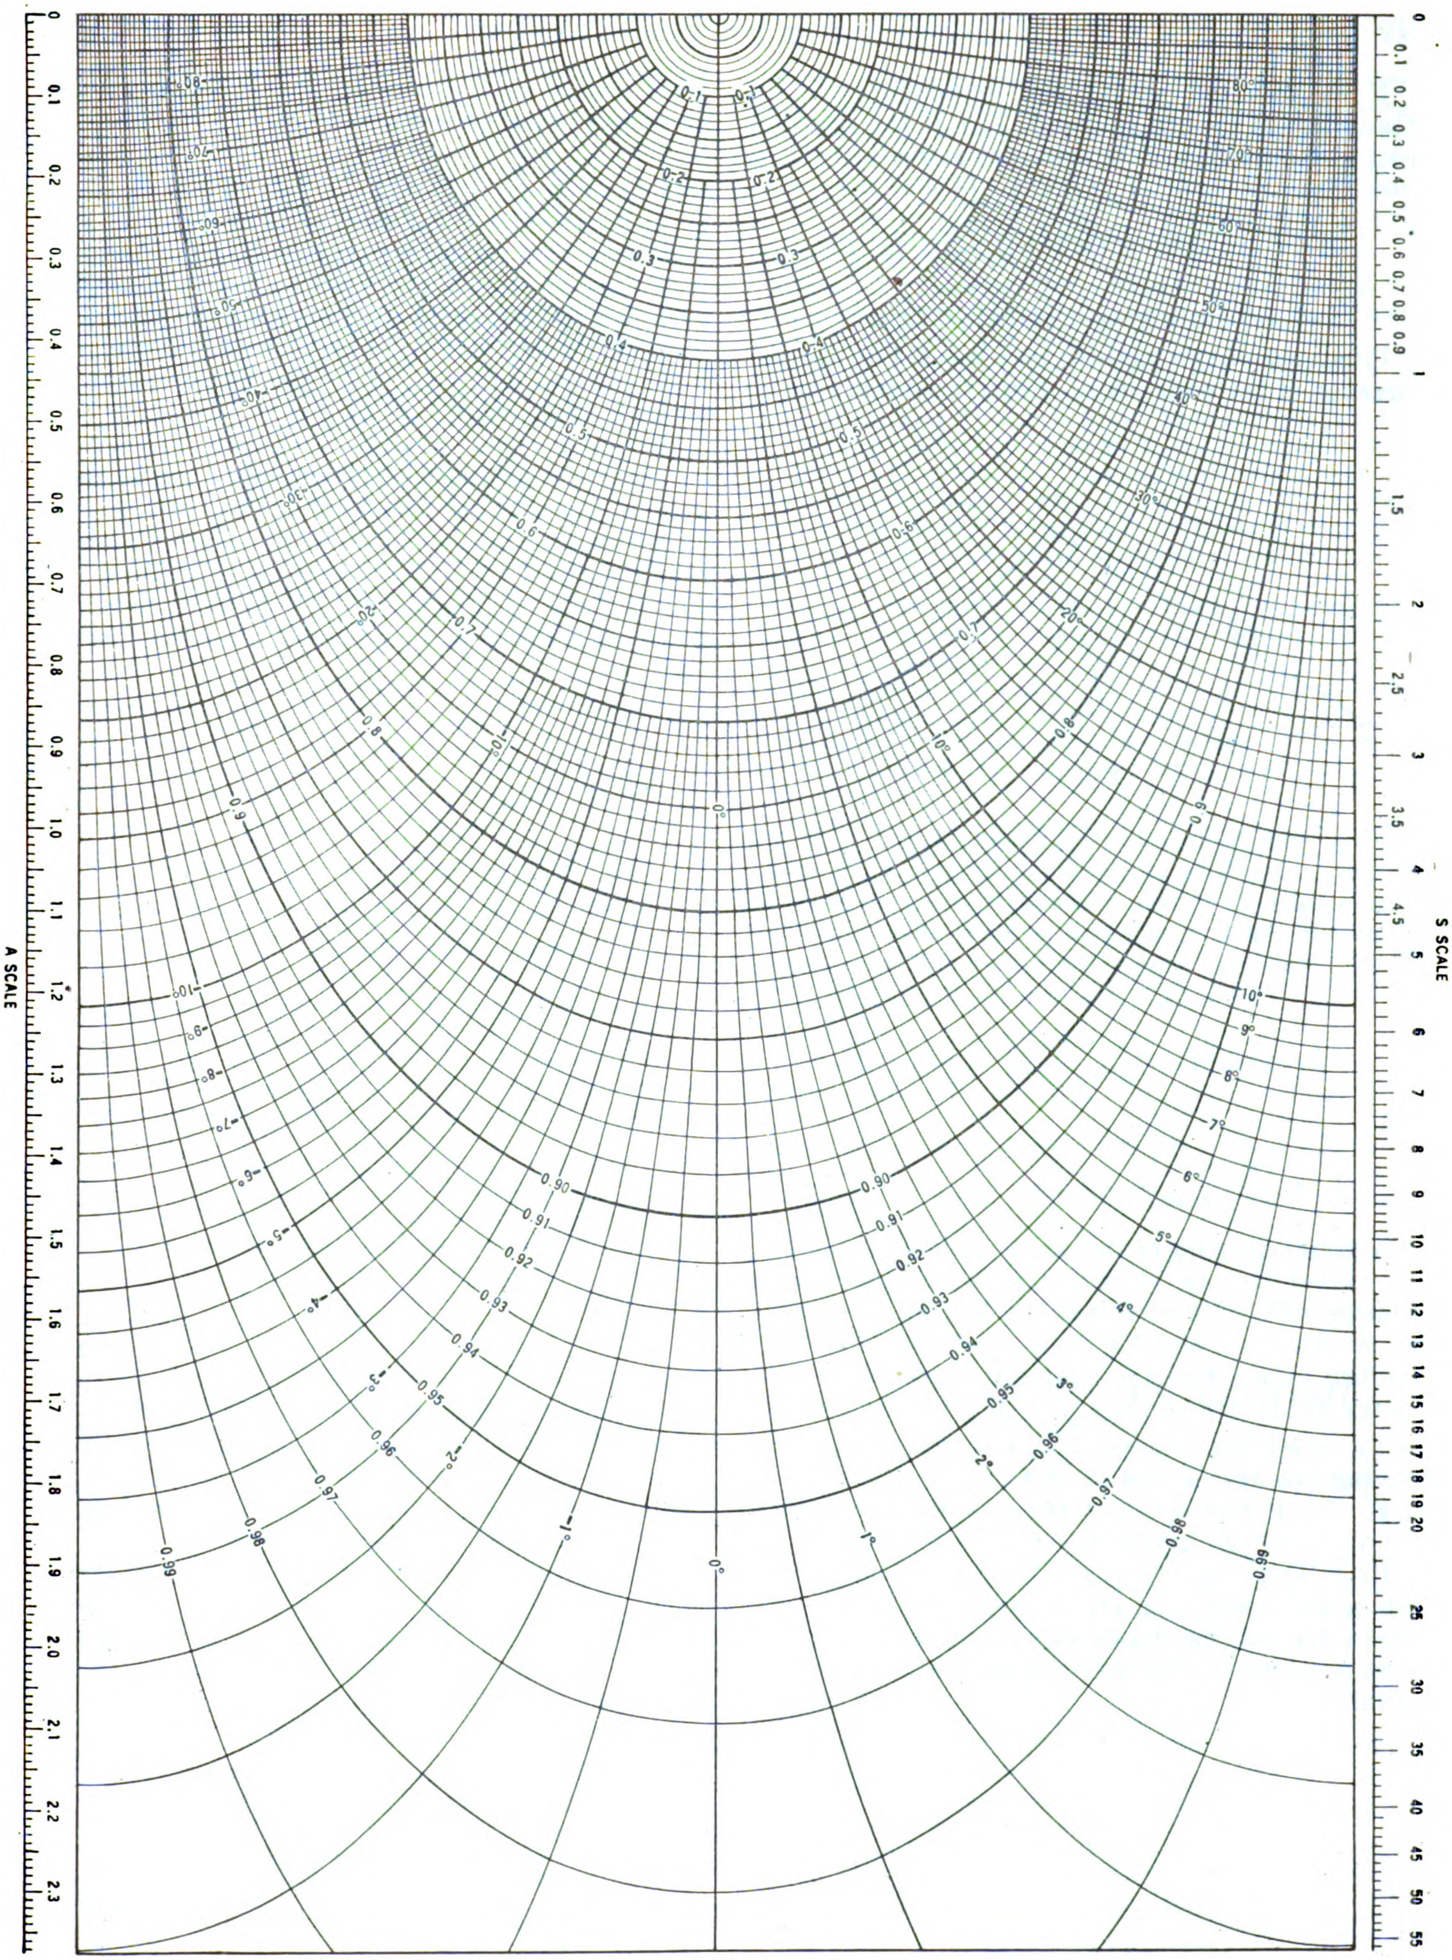
$$1/T = 0.494\,/\underline{78.2^\circ}$$

$$h = \frac{s}{\cos\phi} = \frac{0.16}{\cos 78.2^\circ} = 0.784$$

then by equation **11**,

$$e = e_o\sqrt{\frac{h\,t}{2}} = 60{,}000\sqrt{\frac{0.784}{2 \times 0.494}} = 53{,}500 \text{ volts}$$

$$I = \frac{E}{N\,T} = \frac{53{,}500 \times 0.494\,/\underline{78.2^\circ}}{382.5\,/\underline{-10^\circ}} = 69\,/\underline{88.2^\circ} \text{ amperes, charging current.}$$



Tangent Chart

If we wish the sending end impedance with the distant end of the line grounded, $T_o = 0$, the graphical part of the solution is the same as for the distant end free, with the result, $T = 0.494 \angle 78.2°$

$$E/I = N\,T = 382.5 \angle -10° \times 0.494 \angle 78.2°$$
$$= 189 \angle 68.2° \text{ ohms}$$

Construction of the Work Chart

Either one of two methods may be used in the construction of the work chart. First, the curves may be

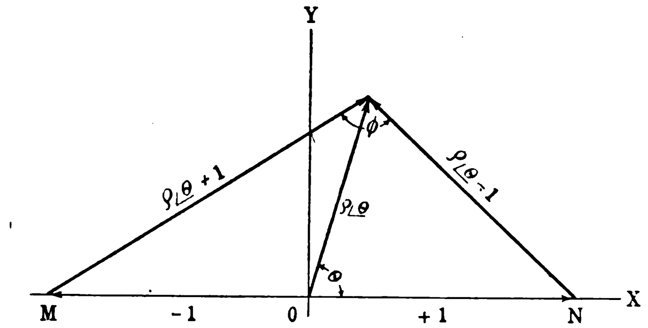


Fig. 10

plotted from their scalar equations, **8** and **9**, in the ordinary way, using tables of the hyperbolic functions and circular functions. Second, the curves may be plotted graphically, using an auxiliary diagram. This method does not require the use of either hyperbolic or circular functions. It is explained as follows.

$$T = \tanh W = \frac{\sigma^{W} - \sigma^{-W}}{\sigma^{W} + \sigma^{-W}} = \frac{\sigma^{2W} - 1}{\sigma^{2W} + 1}$$

Let $\sigma^{2W} = \rho \angle \theta$, then,

$$T = \frac{\rho \angle \theta - 1}{\rho \angle \theta + 1} = t \angle \phi$$

A vector diagram of this equation is shown in Fig. 10. From it may be seen that if we construct a triangle with a base two units in length, the ratio of whose sides is t, and the angle at whose vertex is ϕ, the line drawn from the midpoint of the base to the vertex will be the vector $\rho \angle \theta$. If ϕ is kept constant and t varied, the terminus of ρ will trace out a circle passing through M and N and having its center on $O\,Y$. If t is kept constant and ϕ varied, ρ will trace out another circle having its center on $O\,X$.

Here, then, we have another Argand diagram of orthogonal curves, Fig. 11, in which all the curves are circles and may be drawn with a compass. On such a diagram the A line would appear as a logarithmic spiral.

The connecting link between the circle diagram and the tangent diagram is the relation,

$$\rho \angle \theta = \sigma^{2W} = \sigma^{2u + 2jv}$$

from which,

$$\log \rho = 2\,u \qquad \text{and} \qquad \theta = 2\,v$$

We may thus derive the tangent diagram from the circle diagram, which is relatively easy to construct. That part of the circle diagram which is needed to construct the top half of the tangent chart is included in the segment $A\,B\,N\,D$. This area converts into the rectangle of the chart.

After the circle diagram is drawn a scale of $2\,u = \log \rho$ is accurately constructed by the aid of a table of logarithms. This scale is then laid on the circle diagram with its end at O, the value of $2\,u$ read from the scale, and the corresponding value of $2\,v$ read by means of a protractor. The resulting numbers, plotted in rectangular coordinates, yield the tangent chart.

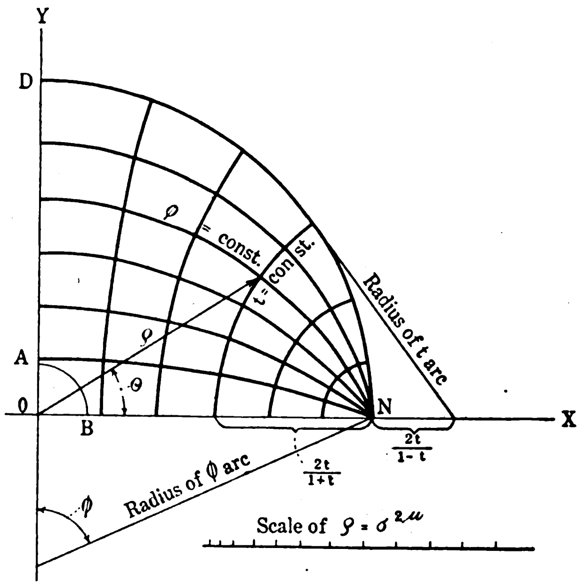

Fig. 11

Conclusion

It is hoped that the foregoing brief description of the tangent chart will interest others in this method with the result that means will be devised for using it in solving transmission line problems of even greater variety than those mentioned.

In conclusion the writer desires to express his sincere thanks to Messrs. Latour and Viard for their very excellent article on this method and to Dr. C. O. Mailloux for advice and suggestions in reference to the preparation of this paper.

A. I. E. E. NOVEMBER MEETING

The 372nd meeting of the Institute will be held on Thursday, November 17, 1921, in the Engineering Societies Building, 33 West 39th Street, New York, N. Y.

The afternoon meeting at 2 p. m., will be a joint session with the Society of Naval Architects and Marine Engineers, forming a part of the annual meeting of that society. The subjects of the session, Electric Auxiliaries, and Electric Propulsion of Ships, should prove of particular interest at this time when competition is growing so keen with the highly efficient ships being put into service by other nations. The two papers to be presented are as follows:

"Electric Auxiliaries on Merchant Ships," by E. D. Dickinson, Marine Department of the General Electric Company.

"Electric Propulsion of Ships," by W. E. Thau, Commercial Engineer of the Westinghouse Electric and Manufacturing Company.

There will also be an evening session of the Institute at 8.15 p. m., which members of the Society of Naval Architects and Marine Engineers and all others interested are cordially invited to attend. This session will be devoted to a lecture on "World Communication," by Alfred N. Goldsmith, Professor of Electrical Engineering, College of the City of New York.

A. I. E. E. MIDWINTER CONVENTION

FEBRUARY 15-17, 1922

The 10th Midwinter convention of the Institute will be held in New York, February 15-17, 1922, in the Engineering Societies Building. This will be the first meeting in 1922 under the new policy adopted by the Board of Directors which prescribes four general meetings of the Institute each year including the annual convention.

While a definite program cannot be announced at this time, the Meetings and Papers Committee has in hand several papers which have been accepted and is prepared to consider for this program any further manuscripts which may be received prior to December 15th.

FUTURE SECTION MEETINGS

Akron.—November 18, 1921. Paper: "A Discussion of the Superpower Survey Report." Speaker: Mr. W. S. Murray, Consulting Engineer, New York City.

December 8, 1921. Papers: "Design and Construction of the Westport Generating Station" by Mr. A. S. Loizeaux, Electrical Engineer, Consolidated Gas Electric Light & Power Co.; "Operating Problems in the Westport Generating Station" by Mr. A. L. Penniman, Superintendent Steam Stations, Consolidated Gas Electric Light & Power Co. The meeting will be held in the Service Building at the Westport Generating Station and will be followed by an inspection trip through the station.

Atlanta.—November 30, 1921. Subject: "Waterwheels."

Kansas City.—November 25, 1921. Subject: "Diesel Engines." Speaker: Mr. C. E. Beck.

Lehigh Valley.—November 10, 1921. At Nazareth, Pa. Subject: "Electrification of Cement Mills."

Minnesota.—November 28, 1921. Subject: "Theory of the Vacuum Tube and its Engineering Applications." Speaker: C. M. Jansky, Jr.

New York.—On the evening of November 14, 1921, a New York Section Meeting of the Institute will be held in the Engineering Societies Building auditorium at 8 p.m. The subject for the evening will be "The Great Lakes—St. Lawrence Canal." This will be a joint meeting of the Metropolitan Sections of the A. S. C. E., the A. I. M. E., the A. S. M. E. and the A. I. E. E. Complete details will be issued to the section membership as soon as available.

Philadelphia.—November 14, 1921. Subject: "The One Best Way to do Work." Speaker: Mr. Frank Gilbreth.

Schenectady.—November 4, 1921. Entertainment and smoker.

November 18, 1921. Subject: "Energy." Speaker: David B. Rushmore.

December 2, 1921. Subject: "Superpower System." Speaker: W. S. Murray.

Toronto.—November 25, 1921. Subject: "Instruments and Measurements."

December 6, 1921. Subject: "Distribution Records and Overhead Distribution."

A. I. E. E. DIRECTORS MEETING

OCTOBER 14, 1921

The regular bi-monthly meeting of the Board of Directors of the American Institute of Electrical Engineers was held at Institute headquarters, New York, on Friday, October 14, 1921, at 3:00 p.m.

There were present: President, Wm. McClellan, Philadelphia; Past-Presidents, A. W. Berresford, Milwaukee, Calvert Townley, New York; Vice-Presidents, W. A. Del Mar, New York, H. W. Eales, St. Louis, N. W. Storer, Pittsburgh, F. R. Ewart, Toronto; Managers, W. I. Slichter, L. F. Morehouse, E. B. Craft, New York, G. Faccioli, Pittsfield, F. D. Newbury, Pittsburgh, L. E. Imlay, Niagara Falls, Harold B. Smith, Worcester; Treasurer, George A. Hamilton, Elizabeth, N. J.; Secretary, F. L. Hutchinson, New York.

Approval by the Finance Committee of monthly bills amounting to $24,105.06, was ratified.

Upon recommendation of the Finance Committee, a budget covering the activities of the Institute for the appropriation year commencing October 1, 1921, was approved.

Upon the recommendation of the Finance Committee, the following resolutions were adopted, establishing a working capital fund for the Institute:

WHEREAS it is desirable to set aside each year a portion of the funds of the Institute as reserve capital, to be used only in certain contingencies, under the direction of the Board of Directors,

RESOLVED that a "Reserve Capital Fund" be established in the accounts of the Institute.

RESOLVED that the $10,000 par value United States Government bonds and the $15,000 par value Wilmington City bonds owned by the Institute be hereby set aside and constituted a "Reserve Capital Fund."

RESOLVED that the Finance Committee of the Institute be authorized to include in each annual budget five per cent (5%) of the income of the Institute to be deposited annually in the Reserve Capital Fund.

RESOLVED that the entire Reserve Capital Fund be subject to withdrawal, in whole or in part, only upon resolution of the Board of Directors, but that the interest upon the fund be deposited in the general funds of the Institute and used for current expenses.

A report was presented of a meeting of the Board of Examiners held September 30, 1921; and the actions taken at that meeting relative to applications for election and transfer were approved. Upon the recommendation of the Board of Examiners the following action was taken upon pending applications: 137 Students were ordered enrolled; 109 applicants were elected to the grade of Associate; 8 applicants were elected to the grade of Member; 1 applicant was elected to the grade of Fellow; 26 applicants were transferred to the grade of Member.

Reports of progress were presented by the Meetings and Papers, Publication, and Coordination Committees, with reference to the plans under way for meetings and publications for the coming year. The direction in which these committees are working was approved in principle by the Board, and further detailed reports will be presented later.

The Standards Committee presented a report including recommendations of a proposed reorganization of the committee. This report was referred to a special committee of five members to be appointed by the President with power to take all steps requisite to formulate definite recommendations to the Board.

In addition to these actions other matters relating to important activities and the general policy of the Institute were discussed; reference to these matters may be found in this and future issues of the JOURNAL under suitable headings.

JOINT RUBBER INSULATION COMMITTEE

The Joint Rubber Insulation Committee, whose well-known specification for 30 per cent Hevea rubber insulation is now almost universally used in the purchase of high grade rubber insulation, has gone out of existence after 10 years of service to the electrical industry.

On the 15th of July, a sub-committee of the Joint Rubber Insulation Committee passed the following resolutions:

WHEREAS, the Joint Rubber Insulation Committee has completed its essential work, and

WHEREAS, its members are no longer in a position to continue its activities, and

WHEREAS, the American Engineering Standards Committee is now the recognized organization for the control of engineering standards, and

WHEREAS, the Constitution of the American Engineering Standards Committee requires that engineering standardization be brought within the influence of that committee through the recognized technical society, such as the American Society for Testing Materials, therefore be it

RESOLVED, that the American Society for Testing Materials be requested to assume responsibility for this work, and be it

RESOLVED, that should the American Society for Testing Materials accept this invitation it be requested to add to the membership of the committee, to which this work will be assigned, a suitable number of members of the Joint Rubber Insulation Committee to insure continuity of efforts, and be it

RESOLVED, that if this consolidation is effected, the Joint Rubber Insulation Committee shall go out of existence and the Secretary shall give due notice to the Technical Press, to the members of the Committee, and others especially interested.

The American Society for Testing Materials acted favorably upon the requests contained in these resolutions at a meeting of its executive committee held October 11th, 1921. The work of the Joint Rubber Insulation Committee will be taken over by committee D-11 on Rubber Products, the chairman of which is Mr. F. M. Farmer, and the Secretary, Mr. C. B. Martin, 466 Lexington Avenue, New York City.

The history of the work of the Joint Rubber Insulation Committee will be found in the report which was printed in the PROCEEDINGS of the American Institute of Electrical Engineers, April 1917, and the *Journal of Industrial and Chemical Engineering*, March 1917. Reprints of the report may be purchased from John Wiley & Sons, New York City. It contains a specification for rubber compound and the details of an analytical procedure which will determine the amount and quality of rubber.

DELEGATION OF AMERICAN ENGINEERS RETURNED FROM ABROAD

REPORT OF JOHN FRITZ MEDAL PRESENTATION CEREMONIES

The engineers forming the American delegation to England and France this summer were guests of honor at a welcome-home dinner given at the Pennsylvania Hotel, New York City, on the evening of October 10. Over two hundred engineers, representing American engineering societies, were present to extend greetings to the delegates. This delegation consisted of Ambrose Swasey, chairman; Charles F. Rand, secretary; Chas. T. Main, Robert A. Cummings and John R. Freeman, representing the American Society of Civil Engineers; Col. Arthur S. Dwight, Wm. D. Kelly and Mr. Rand representing the American Institute of Mining and Metallurgical Engineers; Dr. Ira Hollis, Jesse M. Smith and Mr. Swasey representing the American Society of Mechanical Engineers; and Dr. F. B. Jewett, Dr. A. E. Kennelly and Major General G. O. Squier representing the American Institute of Electrical Engineers.

Mr. J. Vipond Davies, president of the United Engineering Societies, was presiding officer, and in his opening remarks he stated the purpose of the gathering as "primarily to extend greetings to our delegation, but, looking beyond this immediate purpose, there is the greater and broader purpose for which these gentlemen went abroad and to which they have accomplished much, and that is the promotion of international comity and the closer professional relations between our peoples. In honoring our friends, we honor our profession in the broadest sense of a unified world-wide profession of engineering, united in the interest of efficiency and progress."

As to the reasons for the visit abroad he enumerated three distinct contributary causes:

1. To afford British engineers an opportunity to discuss with engineers of this country the amalgamation of engineering societies along the lines of the United Engineering Society and more recently The Federated American Engineering Societies.
2. To show appreciation of the great work done by engineers of England and France in the war.
3. To present John Fritz Medals to Sir Robert Hadfield, of England, and Eugene Schneider, of France.

Before introducing the speakers of the evening Mr. Davies read telegrams and messages received from the recipients of the medals, Mr. Hoover, the Institution of Civil Engineers, of London, the Institutions of Mining and Metallurgy and Mining Engineers, Capt. R. E. Sankey and Magnus Mowett, president and secretary, respectively, of the Institution of Mechanical Engineers, the British Iron and Steel Institute, Societe des Ingenieurs Civils de France, the Engineers Club of London, the Faraday Society, Viscount Bryce, Arthur Neal, member of Parliament from Sheffield, and finally messages from two of the members of the delegation who have remained abroad, Mr. Smith and Dr. Kennelly.

The one from Mr. Jesse Merrick Smith:

The coming together of engineers of all specialties and organizations under such pleasant auspices will greatly advance the profession as a whole.

From Dr. A. E. Kennelly:

May I be counted as if present with you at the dinner although 6000 kilometers distant. I feel assured that the delegation's visit to Paris is very appreciatively remembered here by our French confreres.

The first speaker of the evening was Consul General of Great Britain, Captain G. H. Armstrong. He felt it to be a responsibility of engineers of United States, England and France to draw close together to promote international friendship between these three countries and to assist in restoring happiness and regaining prosperity.

Ambrose Swasey, chairman of the delegation, was next introduced as "Dean of the Engineering Profession." Speaking of the engineers with whom the delegation came in contact while abroad Mr. Swasey said, "Their ideas and their problems as engineers are the same as ours; our problems are theirs. Therefore, we felt that the nearer we could get together, the better it would be for us all." He enlarged upon this thought when, after giving as his general impression that both England and France are well on their way toward a return to normal conditions, he said, in conclusion: "Those countries are near to us; they are nearer to us than ever. Their success means our success; and anything that we can do in bringing not only the engineers but the citizens of those great countries together, that we can join with them in all these great movements for good and righteousness, it will be that much better for the civilization of today."

The secretary, both of the delegation and of the John Fritz Medal Board of Award, Mr. Rand, outlined the experiences of the delegation in London. These included formal and informal functions—luncheons, dinners and receptions—a visit to the National Physical Laboratory, the presentation of the medal to Sir Robert Hadfield, and meetings with the councils of the institution of Mechanical Engineers and the Royal Society. All these events Mr. Rand described in a most entertaining manner. He also spoke of the honors conferred upon members of the delegation by various institutions.

Dr. Jewett, who arrived in London some two months in advance of the other members of the delegation, spoke of the preliminary work connected with their visit, all of which was done with the thought that the event was more than a meeting of engineers and exchange of felicitations between the engineering professions of America and Great Britain. In his association with engineers of Great Britain during this time Dr. Jewett was impressed first by the fact that the leaders in their engineering societies are older men than those leading the activities of the societies of this country and, secondly, by the greater degree of formality observed in the conduct of their engineering meetings.

Two members of the delegation, Mr. Cummings and Mr. Freeman, were able to accept the invitation of the National Society of Engineers of France to go with members of the Society on their annual excursion to the region of the French Alps. Mr. Freeman gave an account of this trip, the object of which was to see the recent developments in the southeastern part of France. Among the developments on which Mr. Freeman commented were those in metallurgy and hydroelectric power in the French Alps, and the new harbor works at Marseilles.

A general description of the visit of the delegation to France was given by Colonel Dwight. The initial gathering was held in the Eiffel Tower where a luncheon was served and brief addresses made. The John Fritz medal was presented to M. Schneider at an evening session of the Societe des Ingenieurs Civils. Later in the month a large part of the deputation met again at the works of Schneider and Company at Le Creusot. Colonel Dwight described briefly this plant, which is the largest and most important of the Schneider works, and the various social functions which took place. He spoke highly of the wonderful esprit de corps found in the Schneider plants which is the result of the care which the company has taken to develop an intelligent and enlightened system of industrial welfare work. Colonel Dwight, who served through the entire period of the war overseas, found marvelous progress in the work of reconstruction since the armistice and praised the wonderful spirit of the people of France which "in thousands of quiet ways is working out a solution of the perplexing problems of peace."

M. Gaston Liebert, consul general of the French Republic, addressed the meeting expressing appreciation of the cooperation and assistance of engineers in this country during the war and summarizing the problems of the French people and the ways in which these problems are being met. He then presented medals which at the request of M. Schneider and in the name of the French Republic, had been struck off for the following engineers:

Mr. Ambrose Swasey, general chairman of the delegation
Mr. Chas. T. Main, chairman, A. S. C. E. delegation
Dr. Ira N. Hollis, chairman, A. S. M. E. delegation
Col. A. S. Dwight, chairman, A. I. M. E. delegation
Dr. F. B. Jewett, chairman, A. I. E. E. delegation
Mr. Geo. S. Webster, president A. S. C. E.
Mr. Edwin Ludlow, president A. I. M. E.
Mr. E. S. Carman, president A. S. M. E.
Dr. W. McClellan, president A. I. E. E.

Following this ceremony Mr. George Clapperton, representing the Institution of Electrical Engineers in London, spoke briefly of the growth of that institution and its desire to work together with engineering bodies of other countries "in softening asperities and leading to that condition of respect, confidence, and esteem between peoples on which rests the hope of mankind."

The final speaker of the evening was Professor Jacques Cavalier, exchange professor from France, who endorsed the idea of the union between the engineers of various countries but emphasized the difficulty resulting from different languages. He believes that the exchange professorship movement may materially contribute to the union of the engineers of the two countries:

The meeting was closed with the announcement of honorary membership conferred upon Mr. Swasey and Mr. Kelly by the Institution of Mining Engineers.

ADDRESSES WANTED

A list of members whose mail has been returned by the Postal Authorites is given below, together with the addresses as they now appear on the Institute records. Any member knowing the present address of any of these members is requested to communicate with the Secretary at 33 West 39th Street.

1.—John A. Dickie, Hotel Washburn, Waukegan, Ill.
2.—Roy L. Ehmann, 4636 North St. Louis Ave., Chicago, Ill.
3.—Wm. J. Epps, Rua Dom Geraldo 80, Rio de Janiero, Brazil, S. A.
4.—G. Foung, Kay Sang & Co., 843 Clay St., SanFrancisco, Cal.
5.—H. L. Francis, F. C. Central Domincano, Puerto Plata, Dominican Republic.
6.—T. J. Hodge, 612 West 137th St., New York, N. Y.
7.—Conrad Jacobson, Hood River, Ore.
8.—Hugo Wm. Jacobson, 1402 East 63rd St., Chicago, Ill.
9.—Howard W. Key, Russell Mfg. Co., 60 East Forsyth St., Atlanta, Ga.
10.—Louis Kunser, Westinghouse Elec Mfg. Co. Swbd. Engg. Dept. K-90, East Pittsburgh, Pa.
11.—G. H. Lindsey, Rosemere Apts., 2255 West 14th St., Los Angeles, Calif.
12.—Chas C. Long, 1109 Arizona Ave., El Paso, Texas.
13.—Geo. C. McCabe, 137 West 86th St., New York, N. Y.
14.—Harry P. Meyer, 327 East 61st St., Los Angeles, Calif.
15.—Chas. Schindler, Great Western Power Co., Crockett, Calif.
16.—D. V. Stoute, 1946 Mosher St., Baltimore, Md.
17.—Frank N. Tucker, 551 East 40th St., Chicago, Ill.
18.—T. S. Young, Yonkers Y. M. C. A., Yonkers, N. Y.

AMERICAN ENGINEERING COUNCIL

SEPTEMBER MEETING

M. E. Cooley Elected President

Mortimer Elwyn Cooley, dean of the College of Engineering and Architecture of the University of Michigan, has been elected president of the American Engineering Council of the Federated American Engineering Societies, it was announced at the meeting of the Executive Board of the Council, held in Washington on September 30, 1921. Dean Cooley assumed office at once.

Mr. Cooley, a past-president of the American Society of Mechanical Engineers, is well-known in the engineering field. He was born in Canandaigua, N. Y., March 28, 1856, and was graduated from the United States Naval Academy in 1878. In 1881 he was detailed to the University of Michigan for three years, under a law which permitted the Secretary of the Navy to detail engineer officers as professors of "Steam Engineering and Iron Shipbuilding," and thus began his long connection with the university covering a period of nearly forty years. After the three years were ended a year's extension of his time was secured; but in 1885 he was ordered to the Pacific Station for duty, whereupon he resigned from the Navy to accept the chair of mechanical engineering at the university. The university also conferred upon him the honorary degree of M. E. He became dean of the College of Engineering in February, 1904, and of the College of Architecture in 1913. He received the degree of LL. D. from the Michigan Agricultural College in 1907; and the degree of Eng. D. from the University of Nebraska in 1911.

During the Spanish War, Dean Cooley served as chief engineer of the *Yosemite*, a converted Morgan liner manned by Michigan State Naval Militia. For a time following the war he was attached to the League Island Navy Yard, first as chief engineer in charge of the machinery of a number of ships and then as assistant chief engineer of the yard.

Mr. Cooley returned to the university in 1899 and during the years following undertook a large amount of important appraisal work, including investigation of the 10,000 miles of Michigan railways valued at $200,000,000, as well as telegraph and telephone lines, plank roads and river improvements. He has been foremost in many lines of public works, serving at various times on committees, such as the Engineering Committee at the Chicago Exposition and the Committee of Awards at the Pan-American Exposition. For sixteen years, 1895 to 1911, he was senior engineer officer of the Michigan State Naval Militia.

Besides being active in the work of the American Society of Mechanical Engineers, of which he was president during 1918-1919, Mr. Cooley has been vice-president of the American Association for the Advancement of Science; director of the American Society of Civil Engineers; vice-president of the Society for the Promotion of Engineering Education; and president of the Michigan Engineering Society.

Mr. Cooley plans to carry out an extensive program in the interest of the public and the profession of engineering with his new and larger opportunity as president of the American Engineering Council.

Progress of the Council's Work

Much important business was transacted by the Executive Board at the Washington meeting. The presiding officers were Calvert W. Townley and J. Parke Channing of New York, vice-presidents.

Department of Public Works. Progress was reported in the direction of establishing a Department of Public Works.

Patents. The Council adopted the report of the Committee on Patents, urging the passage of the Lampert Patent Office Bill to remedy conditions in the Patent Office. A resolution was approved expressing the conviction that this bill "provides the least increases in force and salaries which can possibly stop the retrogression of the Patent Office and enable it to make progress toward recovering an efficient condition, and by increases in the fees for patents, supplies the funds necessary to enable the Patent Office to continue to be self-supporting."

The committee opposed the passage of the Stanley Senate Bill which provides for an amendment to the Patent Act, requiring that patents to aliens be granted with a condition that unless such patents be worked in this country within two years after the granting of the patents, the government may grant licenses under them.

Employment. The report of the special Committee on Employment was discussed at length, resulting in the adoption of the following resolutions:

RESOLVED: That the Executive Board of the American Engineering Council endorses in principle a paid employment service but in the reduced fees to members of organizations supporting said service, and be it further

RESOLVED: That a Committee of five members of the Executive Board be appointed by the chairman and that the Boards of Direction of the four founder societies be requested each to appoint a member of its board in order to form a Joint Committee of the nine members on Engineering Employment in the power to organize an Employment Bureau, on a plan which will invite the cooperation of interested organizations.

Government Contracts. On this question the board made several important recommendations, covering the class of contracts, terms of payment, etc.

Classification of Engineers. The board endorsed the work of the committee on this subject. The chairman of the committee was authorized to appoint a sub-committee to make a comparative study of such proposed legislation as the Lehlbach and Smoot bills in order to present to the Council a final report and recommendation for action.

Annual Meeting in January. The Annual Meeting of the Council will be held in Washington in January. It was decided not to hold an engineering assembly at that time, in view of the business depression.

State Administrative Committee. The organization of a State Administrative Committee in such states as may seem necessary was authorized, in order to secure prompt action in any activity of the Federation.

Other Matters. Two applications for membership were approved, the new members being the Vermont Engineers Society and the Associated Engineers of Spokane.

The resignation of A. C. Oliphant as assistant secretary was announced. Mr. Oliphant is to become associated with M. O. Leighton and Company, consulting engineers of Washington.

The board received the report of Col. A. S. Dwight, the Federation's representative on the deputation which went abroad to confer the John Fritz Medal on Sir Robert Hadfield and Eugene Schneider. British engineers, he stated, manifested an active interest in the Federation, and steps have already been taken to organize the engineers of the British Empire along the same lines.

INDUSTRIAL WASTE

By L. W. WALLACE
Executive Secretary, F. A. E. S.

At the meeting of the Executive Board of the Federated American Engineering Societies held immediately after the organization meeting in Washington in November, 1920, Mr. Hoover suggested the formation of a committee to investigate industrial waste. The Executive Board at once authorized Mr.

Hoover to form such a committee. Late in December a small committee of four or five engineers was brought together by Mr. Hoover. This small committee selected the remaining members of what came to be known as the Committee on Elimination of Waste in Industry. This Committee finally was composed of eighteen engineers, Mr. Hoover being one of them.

In selecting the members of the committee care was taken to secure men of broad experience, clear concepts, and unbiased attitude towards industrial problems. Representatives of managerial, consultant, educational and editorial activities were chosen. The men also were selected so as to be representative of varied industrial activities and contacts.

Early in January the committee met in New York and outlined the policies to be pursued in making investigation of waste in industry. The essence of the plan adopted was to gather quickly such information as might be used to stimulate action and to lay the foundation for other studies. It was believed that a limited yet careful study would not impair the value of the facts disclosed or the significance of the recommendations based upon the same. The point of view of the committee was that its investigation might be compared to that of the preliminary designs of a mechanical engineer, or the work of a reconnoitering part of civil engineers or that of an assay of mining engineers. That is, in all of these matters the chief purpose was to obtain quickly investigation of conditions and of their trend with the idea in mind of making a more detailed and exhaustive work afterwards. So within less than five months the committee completed an assay or analysis of waste in six typical branches in industries and presented a summary of its findings to the Executive Board of American Engineering Council on June 3, 1921 at St. Louis. At that time a condensed news abstract was given to the press. Since that time releases have been made to the daily and technical press covering particular features of the report. In the meantime all of the material has been carefully edited preparatory to printing in book form. The book was scheduled to be ready for distribution on October 29th. The McGraw-Hill Book Company of New York is acting as publisher and distributor for the committee.

The original plan contemplated ten investigations in the field, including transportation and coal mining. Six have been completed. These include, the building trades, men's ready-made clothing, boots and shoes, printing, metal trades and textile manufacturing. In addition to these specific field studies, seven general reports of a statistical character were prepared, each of them dealing with some aspect of industrial waste or its elimination on an extensive or nation-wide basis.

The industries selected for specific study are of great public importance, for their operation directly affects the daily life of everyone. It is believed that the source of waste in these industries may safely be taken as generally characteristic of the whole waste in American industries. It is thought that the findings are not exceptional, and certainly the industries selected were chosen in the belief that they are fairly representative.

The Point of View. At no time did the committee desire to place the blame upon any individual, group or class. Its sole purpose was to endeavor to determine the factors through which waste is occurring and the probable causes for the same. It then desired to make recommendations that would lead to a reduction of the waste that is now occurring. It was believed that the waste occurring was the inevitable result of methods, practises or relationship in industry The committee has had relatively little interest in indicating the various responsibilities for such. In contrast it hoped to indicate the main opportunities for eliminating waste and to indicate what group or class had the greatest opportunity in adopting measures for such elimination.

No attempt has been made to define waste in the academic sense. In the committee's investigations industrial waste has been thought of as part of the material, time and human effort expended in production represented by the difference between average attainments on the one hand and the practical attainable performance on the other, as revealed by the detailed reports. In assaying waste in industry the committee has undertaken to evaluate this difference. This it has established no theoretical standard of performance or excellence but has developed a method of measurement to determine the degree of effective use of those factors within which it was believed waste might be discovered. It has conceived that a given practise is not wasteful until a better has been revealed.

Plan and Study—Questionnaire and Evaluation Sheet

The plan of study followed in each of these six branches of industry investigated was this: At the outset the members of the committee prepared an analysis of those factors and operations in the industry in which waste might be expected to be discovered, provided a comparison was made between average practise and the best known practise. From this analysis, a trial questionnaire was prepared to secure information and quantitative data to permit of comparing the record of one plant with another in the same industry. The questionnaire is composed of 58 main topics and 260 leading questions. This indicates the multiplicity of avenues through which waste may occur.

This trial questionnaire was then used in making a study of one plant in each industry. The results of these trial studies were then brought together, compared, reviewed by the committee and, as a result, a revised questionnaire and an evaluation sheet were prepared, to be used in making the studies upon which the report is based. The revised questionnaire, as used with suggested modifications based on the experience accumulated in its use in field studies, forms an important part of the report.

Calendar. Engineers and managers will be interested in the technique of the plans. One of the significant points was the dispatch with which the work has been organized, conducted and consummated.

The work actually began January 3, 1921. Five months later, June 3, the report was submitted to the Executive Board of the Federated American Engineering Societies. The report covers an assay of 6 industries, a special investigation of the health factors in industry, and a thorough search of all authoritative literature. The committee has also taken on a long-time study of continuous-process manufacture and has stimulated an intensive program for the training of industrial workers.

This extraordinary speed in execution was made possible through splendid cooperation on every hand. The fullest cooperation was obtained from management, labor, engineering and technical societies, public officials and from individual engineers, statisticians, economists, editors, and men in various walks of life. The committee made a practise, insofar as possible, to consult with every known agency, profession, or individual that could give any constructive assistance. At no time was there any pride of authorship. Furthermore, only a wealth of good humor, tolerance, team-play and unselfishness on the part of the committeemen, the field workers and the office force could have accomplished this task. As an evidence of unselfishness the work has been done at cost. The engineering firms that have made the field investigations have done so at cost. They have not charged anything for overhead or profit but have only requested that they be reimbursed for the actual salaries of the men in the field and their traveling expenses. The heads of these firms have spent many days on the work without compensation. Had the committee paid for the service which has kept 40 or 50 engineers in the field for approximately two months, at the ordinary rates for such professional service, the cost would have been many times larger. This remarkable demonstration of speed of execution, tolerance, unselfishness and of untiring efforts is worthy of this consideration given it. It within itself is indicative of what may be done in the elimination of waste in industry through having a definite purpose; careful plans; prescribed schedule; abundant tolerance; unselfish motives; a willingness to do.

Outstanding Features of the Report

Some of the outstanding features are:

First. There is a lack of common terminology and personnel factors. In a very marked degree engineers and factory managers do not speak a common language. The result is confusion. To one group the works manager means one thing, to another an entirely different meaning is conveyed. The public is likewise confused because it has not a common knowledge of the meaning of industrial terms. Take "Collective Bargaining" and "Closed and Open Shop" for examples. It is doubtless true that if people were asked to define or interpret such terms no approximate uniformity would be obtained in reply. The establishment of a common terminology and a clearer definition of industrial words and phrases would lead to the elimination of much misunderstanding throughout industry and therefore to a far greater degree of cooperation.

Second. There is a very great need for the establishment of standard units of measurement for the various factors of management. There are some factors of management for which it would be exceedingly difficult, if not almost impossible, to apply units of measurement, and yet there are many for which it has been done. There has been some progress in the way of establishing standards for gaging individual and group performance, but in a very large degree the practise is limited and it is based on inadequate data and faulty premises. Because scientific method has not been applied, the wage payment accounts for much of the loss. This is likewise true as to standards of performance. Few really know what is reasonable to expect in the way of output.

Third. One of the astounding findings was the disclosure that no agency can furnish complete, timely and authoritative information pertaining to one or all of the essential elements of production. When this is recognized it is not surprising that there have been so many irrational attempts to remedy some of the industrial, economic, social and political problems. Until basic, timely and authoritative data are known no rational remedy can be made to solve such problems as have characterized American industry in recent years. This has been very apparent in connection with unemployment. Even governmental agencies do not agree on this vital question. There is very great need for the establishment of complete, timely and authoritative sources of information pertaining to many of the vital questions involved in the operation of the complex industrial activity of this country.

Fourth. Another interesting and significant finding was lack in several industries of proper agencies whereby there may be a free exchange of information. Many important plants in industry have developed and perfected plans which are not known to the public in general. If such were known in detail the entire industry would be benefited. It is also true that there is a large amount of duplication of expenditure of money in research and for other purposes because of lack of exchange of information. There is a real need for some form of cooperation that will safeguard the interest of the public, yet will permit of a free exchange of information between organizations of a given industry and independent industries. The trade associations properly organized and managed can be an instrument of great usefulness. They should be encouraged after means have been developed whereby the interests of the public may be fully protected.

Fifth. The information gathered through investigation of the committee discloses that there is not as large an amount of waste from labor disputes as generally thought. This, however, is not to be taken to mean that the loss is not material, for it is. It is also true that labor disputes are a serious menace not only to the particular plant or industry but to dependent industries and to the public. The reason why the losses from labor disputes are not as large as commonly thought is perhaps due to the fact that disputes occur in seasonal industries. The loss of production brought about by the strike is frequently made up by the extension of an active period.

Sixth. Another significant finding was that there were no adequate functioning bodies for adjustment of industrial disputes and checking of their waste. Many attempts have been made through legislation to set up legal machinery for adjusting labor disputes. In a number of the states such authorized agencies have not functioned. Twenty-seven states adopted laws creating special State Boards or Commissions for settlement of labor disputes, but it has been only in Kansas that such a Board has functioned to any material extent. The Kansas Court of Industrial Relations has broad powers and has been active, but it has been in existence for too brief a period to draw any rash conclusion as to its effectiveness.

Seventh. One of the outstanding conditions that contributes to industrial waste is the lack of a rational standardization of methods, practises, policies and designs. There is no phase of industry where there is not an almost unlimited opportunity for reducing waste by greater standardization. This can be accomplished without curtailing the individuality.

Eight. Forty-two million men and women employed in the United States lose on the average of six days annually from illness, including non-industrial accidents. There are more than 5,000,000 workers with organic diseases resulting mostly from infection. There are more than 25,000,000 with defective vision requiring correction and it has been found in a number of plants that the increased quantity and quality of production resulting from correcting defective vision has more than paid for the cost of such correction. A great economic waste is occurring through subnormal standards of health and vigor.

Ninth. In 1919 there occurred in industry about 23,000 fatal accidents and about 575,000 non-fatal accidents causing four weeks or more of disability. Statistics show and authorities agree that at least 75 per cent of the accidents in industry can be prevented by the application of proved methods and policies. It is said that in the building industry alone by the adoption of proper methods the waste due to accident may be reduced from 75 to 80 per cent in from two to five years.

Tenth. The lack of industrial research in many industries is the cause for a large industrial waste. American industry has not made adequate use of this important tool in its productive efforts. One of the great needs is the adoption of industrial research as a common agency to bring about economic production.

The report of the committee gives many other interesting and important findings. The detailed information contained in the reports of the engineers that made a study of a specific industry discloses many avenues through which waste is occurring and points out what may be done in a practical way to prevent such large occurrence. The report also makes specific recommendations as to what management, labor and the public may do in the campaign against waste in industry. A study of the report makes it evident that no one escapes responsibility and that every one has an opportunity. In making the investigation and the report the committee desired to stimulate a study of this important matter and to cause all concerned to realize their opportunity. This was one of the important aims and purposes of the entire effort. It is gratifying to know that in part this purpose has been realized, as already evidence of action stimulated by the report has been apparent. A number of leading engineering organizations have given and will give special attention to the findings of the committee. The report has been and will be the basis for many serious discussions. Chambers of Commerce have also taken up the report in their meetings. In almost every instance where this has been done the engineers in the community have been invited in. Another large and important group is to give consideration to the report on the industry in which it is interested at a meeting to be held soon. This organization has invited the engineer that made the study in that particular industry to assist them in devising

means whereby recommendations pertaining to that industry may be put into action. One of the significant outgrowths of the work of the committee is that an engineer who made an investigation in a given industry has been invited in as arbitrator in a labor problem. They were so favorably impressed with the fairness of his findings that they unanimously invited him to act as arbitrator. The work of the committee has come to the attention of a number of important government officials and it has had some influence in certain governmental activities of recent days. It is earnestly hoped that many individuals and groups will give serious consideration to this important report to the end that the campaign for the elimination of waste in American industry may be conducted on a large scale in the months immediately ahead.

The elimination of waste in American industry is an important matter. If American industry is to flourish, if it is to pass successfully through the present crime period and if it is to be able to meet successfully foreign competition and at the same time offer opportunities for advancement to the American workman and to pay such compensation as not to lower the standards of living and retard individual desire of increase in the standards of living, there must be a material reduction in the economic waste that is now occurring.

PERSONAL MENTION

J. T. Travis has opened electrical engineering offices in the Rialto Building, Kansas City, Mo.

V. A. Zehr, consulting engineer of Pekin, Ill., returned on October 17 from a business trip to Europe.

R. I. Maujer is now branch manager of the Cincinnati office of the Cutler-Hammer Manufacturing Company.

C. A. Adams, who has been on part-time leave from his duties at Harvard University, has returned to the university to resume full-time teaching.

Percy A. Robbins, who until recently practised consulting engineering in San Francisco, has retired from active work, and will live in Highland Park, Ill.

Wm. Hamblin Cahoon has left Lockwood, Greene & Company, New York City, and is with Woodwell & Resler, of New York, as electrical engineer.

M. L. Pyle has resigned his position at Bridgeport, Ala., with the Public Light and Power Company, to enter the employ of the Kentucky Utilities Company.

H. P. Westervelt, until recently district manager for the Century Electric Company, Boston, is now with the New England Appliance Company, of Boston.

Edward W. Legier, formerly with the B. F. Goodrich Company, Akron, O., is now located with the American Blower Company, Chicago, as sales engineer.

Carl F. Hofstetter, formerly with the Wagner Electric Manufacturing Company of St. Louis, is located with The Mechanical Appliance Co., Milwaukee.

L. F. Woodruff has left the General Electric Company to become instructor in the electrical engineering department of the Massachusetts Institute of Technology.

Joseph A. Elzi has become instructor in the University of Colorado. He has been located with the Westinghouse Electric & Manufacturing Company of E. Pittsburgh.

Ivar Herlitz is with the Southern Sierras Power Company, Riverside, Cal. During the past year he was in the electrical laboratory of Union College, Schenectady, N. Y.

T. I. Dekle, with the Westinghouse Electric & Manufacturing Company since 1917, has left to enter the service of the Cline Electric Manufacturing Company, Chicago, as control engineer.

E. B. Snyder is with The Ohio Brass Company, Mansfield, Ohio, in the capacity of manager of high-tension sales. He was previously with the Ohio Insulator Company, Barberton, Ohio.

Ben H. Krey, formerly of the General Electric Co., has opened an office at 101 Park Ave., New York, as consulting electrical engineer.

Walter W. Johnson has left the Crete Mining Company, Hibbing, Minn., and is associated with the Pickands Mather Company, Duluth, as electrical engineer in the mining department.

Frank E. Overbey has left the Cutler-Hammer Manufacturing Company of New York to accept the position of assistant superintendent with the Bauer Electric Company of Hartford, Conn.

George R. O. Rutherfurd has become traffic engineer with the Southern California Telephone Company, Los Angeles. He was previously with the Pacific Telephone & Telegraph Company, Sacramento, Cal.

F. V. Armistead, who has been located in the Schenectady office of the General Electric Company, was recently transferred to the Charleston, W. Va., office, for sales work and engineering service in that vicinity.

Louis E. McCoy has been made assistant superintendent of the North Shore Power Company at Three Rivers, Que. Until recently he was engineer draftsman with the Shawinigan Engineering Company, Ltd., Montreal.

James Lynah, formerly president of the Domestic Labor Saving Corporation, New York, has become affiliated with O. A. Barnard in the firm of Barnard-Lynah, Inc., of New York. Mr. Lynah is vice-president of the firm.

Walter H. Weeks, formerly illuminating engineer with the General Electric Company in New York, has become sales engineer in the department of government and corporation sales with the Goodyear Tire & Rubber Company, New York.

Elbert R. Spencer has accepted the position of district manager of The Defiance Motor Truck Company, Defiance, Ohio. He was previously office manager of the Pittsburgh district office of the Allis-Chalmers Manufacturing Company.

HERBERT S. EVANS, who has been associated with the General Electric Company for twenty years, the past ten years as an executive in its foreign department, has left that company to become president of The "Bleh" Company of New York City.

C. R. ALDEN, formerly dean of the school of engineering, Institute of Technology, Detroit, has accepted appointment as dean of the college of engineering, Ohio Northern University, Ada, Ohio.

T. P. STRICKLAND has left the service of the New South Wales Government Railways and Tramways, to become chief engineer of the Melbourne and Metropolitan Tramway Board, Melbourne.

CHARLES P. TOWNSEND, JR., has accepted appointment as superintendent of the Abbeville Water & Electric Plant, Abbeville, S. C. He was previously with the General Electric Company in Atlanta, Ga.

B. B. BESSESEN has become an instructor in the electrical engineering department of Oregon Agricultural College, having left his position as sales engineer with the Manistee Iron Works, in Seattle.

GILBERT C. LAMB, formerly with The American Railways Company, Philadelphia, and the General Electric Company, Schenectady, has become associated with the engineering department of the Condit Electric & Manufacturing Company of So. Boston.

HOWARD H. ADAMS, who has been a cadet engineer with the United Improvement Company, Philadelphia, is now located with the Northern Indiana Gas & Electric Company, at Hammond, Ind., as assistant superintendent in the engineering department.

P. S. JONES, with the Cutler-Hammer Manufacturing Company, has been made branch manager of the Pittsburgh office. A. G. PIERCE, of Pittsburgh, continues as manager of the central district, comprising the Cleveland, Pittsburgh and Cincinnati offices and territory.

JAMES F. NEILD has become associated with the Toronto Transportation Commission, Toronto, Ont., in the capacity of electrical engineer. Mr. Neild was located until recently with the Toronto Railway Company, where he had been superintendent of substations for eight years.

HARRY W. EASTWOOD, who for the past four years has had charge of the Steel Mill and Crane Division of the Cutler-Hammer Manufacturing Company, Cleveland Branch, has been made branch manager, taking the place of Lynn B. Timmerman, who leaves to enter the automobile business in Lima, Ohio.

HENRY C. TOWNSEND announces that the practise of patent, trademark and copyright law heretofore carried on by himself and the late Mr. Charles F. Tischner under the firm name of Townsend & Decker, will be continued by himself and Mr. Frederick B. Townsend under the same firm name.

B. E. FERNOW, JR., has taken up work as instructor in Cornell University. Mr. Fernow was previously located with the Cutler-Hammer Manufacturing Company, Milwaukee, having been chief engineer of the magnet and clutch department since 1917. He is a graduate of Cornell University, and a Fellow of the INSTITUTE.

JOSEPH P. DANKO is now located in Hollywood, Cal., where he is owner of the B & M Electric Shop. Mr. Danko was for several years a radio engineer in the signal service of the War Department, until the past year, during which he was connected with the International Coal Products Corporation, at the Irvington, N. J., plant.

HARRY F. DART has severed his connections with the Rice Institute of Houston, Texas, to accept a position as instructor in the electrical engineering school of Harvard University. During a part of the summer season Mr. Dart was engaged by the International Correspondence Schools of Scranton, Pa., on text-book editing work.

H. S. FOLEY, who for the past four years has been the New York representative of the Compagnie Generale d'Electricite, of Paris, France, and its associated companies, has recently been appointed chief engineer of the Compania Hidroelectrica e Irrigadora del Chapala of Guadalajara, Mexico, and has now gone to that city to take up his new work.

WM. E. WICKENDEN has been transferred from the staff of the Western Electric Company to that of the American Telephone and Telegraph Company, where he will be assistant vice-president. Before entering the service of the Western Electric, Mr. Wickenden was assistant professor of electrical engineering in the Massachusetts Institute of Technology.

J. V. MONTGOMERY is now associated with the Westinghouse Electric and Manufacturing Company as general foreman of electrical construction at the Hell Gate station of the United Electric Light and Power Company, New York City. Mr. Montgomery was until recently an engineer in the electrical division of Dwight P. Robinson and Company, Inc.

NELSON S. MOORE has severed his connection with the Electric Power Equipment Corporation of Philadelphia, and has opened an office in Chicago, under the firm name of Nelson S. Moore & Company, for the purpose of acting as exclusive district representative for manufacturers of high-tension electrical apparatus, offering both engineering and sales service.

W. E. FREEMAN has been appointed acting dean in the College of Engineering of the University of Kentucky. For the past year Mr. Freeman has been supervisor of commercial training with the Westinghouse Electric & Manufacturing Company at East Pittsburgh, Pa., but previous to that time was head of the department of electrical engineering in the University of Kentucky.

J. G. ZIMMERMAN and A. L. SUDDUTH, of Milwaukee, Wis., have formed The Z-S Company, a partnership for research and development work, and for completing or perfecting inventions, especially in the line of ignition engineering. Mr. Zimmerman is instructor in ignition at the School of Engineering of Milwaukee and Mr. Sudduth is laboratory instructor in ignition at the same school.

J. G. KOPPEL, formerly electrical and mechanical engineer of the Sault Ste. Marie Bridge Company, Michigan, and lately construction engineer with the B. F. Goodrich Rubber Company, Akron, Ohio, having left that company on account of the de-

pression last fall, has been in Oregon since, and has recently organized the Eugene Machine & Auto Company, Eugene, Oregon, of which he is president.

D. McFarlan Moore has recently become a vice-president of the Illuminating Engineering Society. Mr. Moore has been well-known in electrical circles for a number of years, especially in connection with his vacuum-tube lighting system. He is at present manager of the Moore Light Department of the General Electric Company at Harrison, N. J. He is a Fellow of the Institute and has served in other technical bodies.

R. W. Stovel has recently joined with H. A. Brinkerhoff in the firm of Stovel & Brinkerhoff, engineers and constructors, New York City. Mr. Stovel is a graduate of McGill University, from which he received the degree of M. S. in 1900. He has had a wide experience in electrical and mechanical engineering, including a number of years with Westinghouse, Church, Kerr & Company, where he was managing engineer for some time. During the war he was with the A. E. F. as Lt. Colonel in charge of the mechanical and electrical equipment at all ports used by the American Army in France. Mr. Brinkerhoff is a mechanical engineer who has had responsible charge of many large engineering and construction undertakings.

OBITUARY

Dr. Emil A. Budde, prominent German scientist and electrical engineer, and an Honorary Member of the Institute since 1912, died recently at the age of 80. He was educated at the gymnasiums of Arnsberg and Dusseldorf and at the University of Bonn, where after graduation he became assistant in mathematics and physics. During the Franco-German war he was a war correspondent for the *Koln Zeitung*, later becoming editor and then foreign correspondent. In 1887 he opened a private laboratory in Berlin and in 1892 was appointed physicist with the Siemens & Halske Company, of which organization he was director from 1893 on, for many years. He contributed largely to German scientific publications and was the author of numerous books on physics, mechanics, philosophy, etc. Dr. Budde was official delegate for Germany with Helmholtz at the Chicago International Electrical Congress in 1893. He was one of the founders of the Verband Deutscher-Elec trotechniker of which he served as secretary and later president. He was president of the International Electrotechnical Commission succeeding Dr. Elihu Thomson.

Alexander M. Gray, professor and head of the electrical engineering department at Cornell University, died on October 13, 1921, after a prolonged illness. Prof. Gray was born in Edinburgh, Scotland, in 1882. He took the mechanical engineering course at Heriot Watt College, Edinburgh, and was awarded a diploma. He then entered Edinburgh University and was graduated with the degree of B. Sc. in Civil Engineering. In 1906 he completed the electrical engineering course at McGill University, Montreal, receiving the degree of B. Sc. He then spent three years as a designer of electrical machinery with the Bullock Electric Company, and two years as head of the a-c. motor department of the Allis-Chalmers Company. He left this work to become assistant professor of electrical engineering at McGill University and in 1915 accepted the position as head of the same department at Cornell. Prof. Gray was the author of several books on electrical machine design. During his connection with the Institute, of which he became an Associate in 1906 and a Member in 1913, he served upon the Educational, Electrical Machinery and Meetings & Papers Committees, and also the Committee on Student Branches.

Percy C. Henry, superintendent of distribution for the New England Power Company, was killed at the Worcester, Mass., substation on September 9, 1921. His death was caused accidentally during the demonstration of a device designed for the testing of pin-type insulators. Mr. H. B. Bush, of Cleveland, Ohio, inventor and demonstrator of the device, was also instantly killed. Mr. Henry had been with the New England Power Company for the past year. He was born in Bourbon, Ill., October 22, 1889, and was graduated from Purdue University, the first year and a half of his college work, however, having been done at the Massachusetts Institute of Technology. After some experience with the Commonwealth Edison Company of Chicago and the Illinois Steel Company in Gary, Ind., he became electrical superintendent of the Massena, N. Y., plant of the Aluminum Company of America, which position he left to become connected with the New England Power Company. Mr. Henry joined the Institute first as a student member, becoming an Associate in 1916.

Earl S. James, assistant superintendent of the electrical department of the Oklahoma Gas and Electric Company, died August 28, 1921. Mr. James had been with this company for fourteen years, starting as an apprentice in the electrical testing and repair department. Born in Bosworth, Mo., in 1891, he finished high school, and then took the I. C. S. course in electrical engineering. He became an Associate of the Institute in 1920.

Winthrop G. Bushnell died of heart disease at his home in New Haven, Conn., on October 23, 1921. Mr. Bushnell has been prominent in the development of public utilities, particularly in Connecticut, where he merged the New Milford Power Company and the Falls Village Water Power Company into the Connecticut Power Company, now supplying power to a large part of the state. He was also connected with the successful development of power projects in Cuba. He was director for the Delaware Aircraft Company. Mr. Bushnell was a graduate of Yale, 1888, and for many years was connected with the General Electric Company and its predecessors. His father, Cornelius S. Bushnell, financed the building of the *Monitor* of Civil War fame. Mr. Bushnell had been an Associate of the Institute since 1903.

Dr. Joseph W. Richards, professor of metallurgy at Lehigh University, died suddenly of heart disease at his home in Bethlehem, Pa., on October 10, 1921. Born in Oldburg, England, fifty-seven years ago, Dr. Richards come to this country as a boy and was educated here, attending Lehigh University. He began teaching at Lehigh in 1887. In 1902 he was active in the formation of the American Electrochemical Society, becoming its first president; and in many other ways has been active in his profession, being recognized as one of the foremost chemists in this country, and acquiring an international reputation as a metallurgist, especially known as an authority on aluminum. He was the author of many scientific works, and was one of the founders of *Electrochemical Industry*, the forerunner of *Chemical and Metallurgical Engineering.*

Albert C. Schweizer. Word has been received of the recent death of Albert C. Schweizer of the New York Edison Company. Mr. Schweizer started with this company when a boy, in 1894. His last position was that of deputy assistant superintendent in the office of the general superintendent of distributing stations, where his work pertaining to methods and systems of d-c. feeder distribution was considered remarkable; and the company felt that his untimely death at the age of 41 cut short a career of much promise. Mr. Schweizer was a graduate of Cooper Union which he attended while retaining his position with the New York Edison Company. He became an Associate of the Institute in 1920.

ENGINEERING SOCIETIES LIBRARY

The library is a cooperative activity of the American Institute of Electrical Engineers, the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers and the American Society of Mechanical Engineers. It is administered for these Founder Societies by the United Engineering Society, as a public reference library of engineering and the allied sciences. It contains 150,000 volumes and pamphlets and receives currently most of the important periodicals in its field. It is housed in the Engineering Societies Building, 29 West Thirty-ninth St., New York.

In order to place the resources of the Library at the disposal of those unable to visit it in person, the Library is prepared to furnish lists of references to engineering subjects, copies or translations of articles, and similar assistance. Charges sufficient to cover the cost of this work are made.

The Director of the Library will gladly give information concerning charges for the various kinds of service to those interested. In asking for information, letters should be made as definite as possible, so that the investigator may understand clearly what is desired.

The library is open from 9 a. m. to 10 p. m. on all week days except holidays throughout the year except during July and August when the hours are 9 a. m. to 6 p. m.

BOOK NOTICES (Sept. 1-30, 1921)

Unless otherwise specified, books in this list have been presented by the publishers. The Society does not assume responsibility for any statements made; these are taken from the preface or the text of the book.

All the books listed may be consulted in the Engineering Societies Library.

A. S. T. M. Standards, 1921.

Phila., American Society for Testing Materials. 890 pp., illus., 9 x 6 in., cloth. $10.00.

The 1921 volume of standards contains the specifications and methods of testing approved by the Society. These number 160, and have to do with a variety of materials—ferrous and non-ferrous metals, cement, lime, gypsum and clay products, preservative coatings, road materials, coal and coke, timber, timber preservatives, etc. Nearly one-half of the standards have been revised since the last edition appeared, or are new.

Alternating Currents.

By Carl Edward Magnusson. Second edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1921. 559 pp., illus., 9 x 6 in., cloth, $4.50.

A presentation of the fundamental principles of alternating-current phenomena, with illustrations of their application to industrial problems, intended to aid the student in gaining clear concepts of what actually takes place in alternating-current machinery, to explain the relations between the factors involved and to express the physical facts in mathematical forms in such a manner that he shall understand the equations and be able to use them rationally in the solution of industrial problems.

America's Power Resources.

By Chester G. Gilbert and Joseph E. Pogue. N. Y., The Century Co., 1921. 326 pp., illus., 8 x 5 in., cloth. $2.50.

An attempt to interpret the importance attaching to the energy resources, coal, oil, natural gas and waterpower, to point to the shortcomings in the way they are handled, to outline the changes in the administration of energy which are bound to come into play if due social and industrial progress is to be attained, and to indicate the avenues of advance along which constructive efforts should be applied.

The material presented is largely the result of investigations by the authors, brought out from time to time as special papers, emanating mostly from the Division of Mineral Technology, United States National Museum, and more popularly presented here in a unified and less technical form.

Analytic Geometry, with Introductory Chapter on the Calculus.

By Claude Irwin Palmer and William Charles Krathwohl. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1921. 347 pp., 8 x 5 in., cloth. $2.50.

The object of this book is to present analytic geometry to the student in as natural and simple a manner as possible without losing mathematical rigor. It is based on the course given at the Armour Institute of Technology.

Automatic Telephony.

By Arthur Bessey Smith and Wilson Lee Campbell. Second edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1921. 430 pp., illus., diagrs., 9 x 6 in., cloth. $5.00.

The method adopted is to describe fully the typical circuits and apparatus of the Strowger type, and to outline briefly the other important systems. By this method it has been possible to explain the principles and methods fully enough for their application to other makes of equipment, without attempting to narrate the practise of all manufacturers in detail.

This edition is radically changed from the previous one, by the elimination of obsolete matter and the introduction of new material.

Concrete Work.

By William Kendrick Hatt and Walter C. Voss. Vol. 2. N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall, Ltd., 1921. 206 pp., illus., 8 x 5 in., cloth. $2.00.

The second volume of this practical text-book is a systematic course in the application of the fundamentals of concrete work, as set forth in volume one, to a series of representative examples. The complete work forms an unusually practical course in concrete construction.

A Dictionary of Applied Chemistry.

By Sir Edward Thorpe. Vol. 2. Revised and enlarged edition. Lond. and N. Y., Longmans, Green and Co., 1921. 717 pp., illus., 9 x 6 in., cloth. $20.00.

The second volume of this welcome revision of the standard reference work in English on applied chemistry to appear during 1921 carries the work to the subject of Explosion. Under the direction of Sir Edward Thrope, the work has been done by a long list of competent authorities, who have signed all the longer articles. The work, when complete, promises to be about one-third larger than before.

E. M. F. Electrical Year Book.

Edited by Frank H. Bernhard. First annual edition, 1921. Chicago, Electrical Trade Publishing Co. 1406 pp., illus., 12 x 9 in., cloth. $10.00.

A combined encyclopedia, dictionary and trade director of the electrical industry, prepared by a large editorial staff, and containing a great amount of up-to-date information of the kind most sought by those connected with electrical enterprises or using electricity. The volume is arranged alphabetically tnd is a convenient reference book on matters of theoretical, aechnical and industrial interest.

Electric Furnace.

By J. N. Pring. Lond. and N. Y., Longmans, Green & Co., 1921. (Monographs on industrial chemistry.) 485 pp., plates, illus., 9 x 6 in., cloth. $10.50.

Although the most noteworthy branches of the electrochemical and electrometallurgical industries have been described in a number of publications, the present rapid progress of these enterprises demands a frequent revision and extension of the literature. This volume is an additional contribution to the general technical discussion of the position and prospects of high-temperature industrial chemistry.

The author reviews the history and principles of the electric furnace and describes the types in use. Current supply, transformers and the measurement of high temperatures are treated and the use of the electric furnace in the metallurgy and chemistry of the [illegible] metals is described. Attention is also given to furnace design and to the economic aspects of electrochemical processes. [illegible] bibliography is appended.

ELEMENTS OF SPECIFICATION WRITING.

By Richard Shelton Kirby. Second edition, revised. N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall, Ltd., 1921. 153 pp., 9 x 6 in., cloth. $1.50.

This is a text-book on the art of specification writing, not a collection of specifications. It is based on the course given by the author in the Sheffield Scientific School of Yale University. The revision has been made with the purpose of modernizing the book and of making it more useful for those outside the profession of civil engineering.

A FIRST COURSE IN ANALYTICAL GEOMETRY.

By Charles N. Schmall. Second edition, enlarged. N. Y., D. Van Nostrand Co., 1921. 338 pp., 8 x 5 in., cloth. $2.25.

A course of moderate scope, designed for use in colleges and scientific schools, and as an introduction to advanced courses.

INDUCTION MOTOR AND OTHER ALTERNATING-CURRENT MOTORS

By B. A. Behrend. Second edition, revised and enlarged. N. Y. and Lond., McGraw-Hill Book Co., Inc. 1921. 272 pp., ports., diagrs., 9 x 6 in., cloth. $4.00.

This work appeared first in 1901 and is based on a series of lectures delivered at the University of Wisconsin during the preceding year. This second edition, twenty years later, has been expanded from 105 to 272 pages and thoroughly revised to represent the author's present opinions on its subject.

The book is not meant to be encyclopedic. It is, in the words of the author, "essentially the work of an engineer, who has had the good fortune to have been actively associated with the art of electrical engineering through almost three decades and who has had a part in the development of the machines about which he writes."

He thus addresses himself to his fellow-engineers, revealing the methods which he has followed in the design and construction of alternating-current motors, of which literally millions of horse power were executed under his direction.

POWER HOUSE DESIGN.

By Sir John F. C. Snell. Second edition. Lond. and N. Y., Longmans, Green & Co., 1921. (Electrical engineering series.) 535 pp., illus., diagrs., tables, 9 x 6 in., cloth. $14.00.

In preparing this book, the author has drawn upon his own experience of over twenty years and has collected and classified the experience of other engineers. The information thus acquired has been carefully sifted and condensed in the present volume, which the writer believes to contain all the requisite practical information on its subject. The principles and information given cover the design and equipment of central stations and isolated plants for supplying light and power to cities, factories, mines, railroads, etc., and are accompanied by typical examples of modern installations. This edition has been thoroughly revised and to a considerable extent rewritten.

PRACTICAL TRACK MAINTENANCE.

By Kenneth L. Van Auken. Second edition. Chicago, Railway Educational Press, Inc., 1921. 274 pp., illus., 8 x 5 in., cloth. $2.50.

Van Auken's book is designed to cover the essentials of routine section work, as approved by practical track men of varied experience. It is therefore adapted for use as a guide in the every day work of the foreman or supervisor. The second edition is apparently an unchanged reprint of the first.

THERMODYNAMICS.

By J. E. Emsweiler. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1921. 266 pp., diagrs., 9 x 6 in., cloth. $3.00.

An attempt to present the subject progressively so that the reader may easily recognize the relation of each new demonstration to the whole. For this purpose the order of presentation is changed from that usually employed. Steam is placed first, followed by vapor refrigeration, after which the permanent gases, mixtures and air heat engines are studied. Formal discussion of the laws of thermodynamics and the kinetic theory of gases is postponed until the close of the book.

WHITTAKER'S ELECTRICAL ENGINEER'S POCKET-BOOK.

Edited by R. E. Neale. Fourth edition. Lond. and N. Y., Sir. Isaac Pitman & Sons, Ltd., 1920. 671 pp., illus., 6 x 4 in., [illegible]. $4.00.

This edition, the first in nine years, has been entirely rewritten. Its scope has been materially extended and the assistance of several specialists secured in order that the treatment of each subject might accord with the latest practise.

The book is intended, while covering the range of matter and having the convenience of reference commonly expected from a pocket-book, also to furnish an up-to-date synopsis of each subject which will have the coherency and wealth of detail usually found only in text-books, so that the volume may be equally useful for systematic reading and for reference. The field covered is broadly that of industrial electrical engineering.

YEAR BOOK OF THE AMERICAN BUREAU OF METAL STATISTICS.

First annual issue, 1920. 62 pp., tables, 10 x 8 in., paper.

This book, prepared under the direction of W. R. Ingalls, was designed to be a compilation of the statistics of the production, consumption and commercial movements of copper, lead and zinc in the principal countries of the world, covering, in general, the last ten years. The figures given are taken from the best available government and commercial sources, and great care has been taken to insure accuracy. The countries included are the United States, Great Britain, France, Belgium, Sweden, Italy and Japan.

SECTION AND BRANCH MEETINGS

PAST SECTION MEETINGS

Akron.—September 28, 1921. Paper: "Electric Arc Welding." Author: Mr. A. F. Davis, of the Lincoln Motor Company. Attendance 20.

Atlanta.—September 29, 1921, Chamber of Commerce Building. Subject: "Radio Telephony and Wireless Telegraphy." Speaker: Mr. H. E. Bussey, District Manager of the General Electric Company. Attendance 37.

Chicago.—October 3, 1921, Rooms of the Western Society of Engineers. Joint meeting with the Western Society of Engineers. Subject: "A Review of the Northwestern Elevator Explosion." Speaker: Mr. David J. Price, Engineer in Charge of Development Work, Bureau of Chemistry, U. S. Dept. of Agriculture. Attendance 270.

Cincinnati.—September 15, 1921, Literary Club Rooms. Joint meeting with the Engineers Club. Subject: "Radio Communication." Speaker: Professor S. M. Kintner, of the Radio Engineering Department of the Westinghouse Electric & Manufacturing Company. Attendance 150.

Connecticut.—September 21, 1921. The meeting was preceded by a visit to the principal Hartford Exchange of the S. N. E. Telephone Company, followed by a dinner at the Hartford Club. (1) Mr. E. H. Everit, Chief Engineer of the S. N. E. Telephone Company, explained the evolution of machine switching and gave interesting instances of the influence of the operator's psychology on the form taken by the mechanical equipment. (2) Mr. Samuel Ferguson, Vice-President of the Hartford Electric Light Company, analyzed the reports of the Hydroelectric Power Commission of Ontario for the purpose of decomposing the operating costs into elements associable with the remarkably low domestic rates in the Ontario towns. (3) Mr. R. W. Simpson, of the engineering staff of the Travelers Insurance Company of Hartford, emphasized the importance of safeguarding electrical equipment in industrial plants. (4) Mr. L. W. W. Morrow, delegate to the Salt Lake City Convention of the A. I. E. E., reported on the proceedings of the Convention. Attendance 80.

Detroit-Ann Arbor.—September 16, 1921, Detroit Board of Commerce. Joint meeting of all Detroit Technical Societies. The meeting was called for the purpose of organizing The Affiliated Technical Society of Detroit and discussing the proposed Constitution. Attendance 300.

Fort Wayne.—September 27, 1921, G. E. Club Rooms. (1) Mr. R. H. Chadwick, Chairman of the Section, talked briefly on the aims of the Section for the coming season, and asked for cooperation between all of the members and the officers. (2) Mr. J. J. Kline, delegate to the A. I. E. E. Salt Lake City Convention, described one of the trips taken by the delegates to the Utah Copper Company's mine. (3) Mr. Howard Miller, Chairman of the Meetings and Papers Committee, outlined the program for the coming year as far as it has been arranged. (4) Mr. P. M. Staehle, Chairman of the Membership Committee, spoke on the advantages of belonging to an association of engineers and urged all interested men to become members of the Section. The Entertainment Committee then took charge of the program, which included violin and vocal solos. Refreshments were served. Attendance 50.

Kansas City.—September 30, 1921, University Club. Appointment of Membership Committee, and report of Chairman Shaad on the A. I. E. E. Salt Lake City Convention. Speaker of the evening: Dean McCaustland, of the University of Missouri. Subject: "Duties an Engineer Owes to His Community." Attendance 19.

Lehigh Valley.—September 29, 1921, Hotel Allen, Allentown, Pa. Dinner followed by a meeting at which Mr. H. W. Smith, of the Westinghouse Electric & Manufacturing Company, E. Pittsburgh, presented an illustrated paper on the subject of "Transmission and Distribution of Electrical Energy." Attendance 94.

Los Angeles.—October 1, 1921, U. S. S. *Tennessee*, Los Angeles Harbor. The members of the A. I. E. E. Section and the Los Angeles Sections of the other technical societies were invited to visit and inspect the U. S. S. *Tennessee*, an electrically driven battleship, in the Los Angeles Harbor. Guests were divided into parties of ten or twelve, each party being in charge of one of the ship's officers. Attendance 250.

Minnesota.—October 3, 1921, Elks Club, Minneapolis. Joint meeting with local Section of A. S. M. E. Subject: "The Valuation of Public Utilities." Speaker: Mr. Delos F. Wilcox. Attendance 64.

New York.—On the evening of Wednesday, October 19, 1921 the New York Section of the Institute held a joint session with the Metropolitan Sections of the A. S. C. E., the A. I. M. E., and the A. S. M. E. The idea of holding joint sessions is a continuation of the policy adopted last year, which proved so successful, and if the attendance at this first meeting, over 1275, is a criterion, this year's meetings will prove even more successful. The subject for the evening, "Financing of Large Engineering Projects" by Arthur B. Leach of A. B. Leach & Co., Bankers, New York, proved particularly interesting. Mr. Leach devoted himself to drawing a picture of conditions as they existed in 1914 previous to the war, when the public confidence in the soundness of investments in large engineering undertakings had been established and brought that picture through all its phases, down to the present conditions. He stated that in order to regain public confidence it will be necessary to make our existing work efficient before undertaking new projects.

Immediately following this subject, Mr. Philip Cabot of White, Weld & Co., Boston, spoke on "The Engineer, A Failure as a Financial Manager" claiming that in a majority of cases the engineer both through education and natural attainments was unfitted to act as a manager, lacking chiefly an ability to visualize the future of proposed projects.

A lively discussion followed which was participated in by Calvert Townley, John H. Williams, Lewis H. Nash, A. Karminsky, B. Stevens, after which Chairman Farley Osgood reviewed the various presentations in a general way.

Pittsburgh.—October 11, 1921, Chamber of Commerce Auditorium. Subject: "Automatic Control of Motor-Generator Sets for Edison Direct-Current Service." Speaker: Mr. R. J. Wensley, of the Westinghouse Electric & Manufacturing Company, E. Pittsburgh. Mr. N. W. Storer, Vice-President of District No. 2, also addressed the meeting on the subject of more enthusiasm and greater cooperation in making the local Sections a success. Attendance 106.

Portland.—September 13, 1921, University Club. Joint meeting of the Portland Sections of the A. I. E. E. and N. E. L. A. Subject: "Regulations Under the Oregon and Washington Utilities Acts." Speaker: Mr. J. A. Laing, Vice-President of the Pacific Power & Light Company. Attendance 60.

Providence.—October 7, 1921, Providence Engineering Society. Subject: "European Practise in Electrical Switchgear and Transmission." Speaker: Mr. C. M. Moss, of the Westinghouse Electric & Manufacturing Company. The talk was illustrated by slides. Attendance 15.

Schenectady.—October 7, 1921, Edison Club Hall. Subject: "Super-Engineering." Speaker: Mr. William McClellan, President of the A. I. E. E. Attendance 200.

Seattle.—September 20, 1921, Blanc's Cafe. Annual dinner and get-together meeting. Reports were made by Chairmen of Meetings and Papers Committee and Membership Committee. During the evening a demonstration of "Wired Wireless Telephony" was given by Mr. Kalin. The Entertainment Committee arranged to have many humorous phone calls received by Messrs. Scott and Terrell. These were attached to loud speaking telephones, where they could be enjoyed by all. Prominent local engineers were called upon for an address. Chairman Growdon reported on his trip to the Salt Lake City Convention. Mr. J. B. Cox, Engineer with the General Electric Company, spoke at length on Railway Electrification on the Pacific Northwest. Attendance 57.

Spokane.—September 23, 1921, Davenport Hotel. Report of the Annual Convention by Mr. H. V. Carpenter, Section's delegate. Attendance 11.

Toronto.—September 30, 1921, C & M Building, Toronto University. Subject: "Transmission Systems." Speaker: Mr. H. C. Don Carlos, of the Hydroelectric Power Commission of Ontario. Attendance 109.

Urbana.—October 7, 1921. Subject: "European High Power Radio Stations." Speaker: Professor J. T. Tykociner. Attendance 137.

Utah.—September 21, 1921, Commercial Club. Joint meeting with the Utah Society of Engineers. Paper: "Electrolytic Production of Zinc." Author: Mr. J. T. Ellsworth, Superintendent of Zinc Plants, Judge Smelting, Mining & Refining Company. The paper outlined the general principles involved and the methods used in extracting zinc from the Park City ores. The various problems involved in the electrolytic deposition of zinc, including the tendency for other metals to deposit with the zinc, were discussed. The future of the zinc industry and some of the problems yet to be solved in electrolytic reduction were discussed. Attendance 80.

Vancouver.—September 9, 1921, Board of Trade Building. Mr. C. N. Beebe, Section delegate to the Salt Lake City Convention, gave an address outlining some of the Sections Committee discussions, and some of the papers submitted. Mr. Beebe was followed by Mr. F. W. MacNeill, who was also at the Convention, and a discussion was entered into by almost all present. Attendance 11.

Worcester.—September 29, 1921, E. E. Building, W. P. I. Paper: "Radio Telephony." Speaker: Mr. W. R. G. Baker, General Electric Company. Illustrated with stereopticon slides. Attendance 115.

PAST BRANCH MEETINGS

Alabama Polytechnic Institute.—September 22, 1921. Talk by Professors McIlvaine and Hill on the advantages of the A. I. E. E. Attendance 88.

Armour Institute of Technology.—September 29, 1921. Subjects: "Activities of the American Institute of Electrical Engineers" by R. P. Burns; "Advantages Derived by Members of the A. I. E. E." by Professor Snow. Attendance 58.

Bucknell University.—September 28, 1921. Election of officers as follows: Chairman, Freeman T. Tingley; Vice-Chairman, E. LaRue Worthington; Secretary-Treasurer, John A. Ammerman. Attendance 15.

October 10, 1921. Subjects: "History of the Growth of the Electrical Engineering Course in Bucknell University" by Professor W. C. Rhodes; "Advantages of the American Institute of Electrical Engineers" by Professor Irland; "Advantages of the Bucknell Branch of the A. I. E. E. to the Electrical Students" by President Tingley. Attendance 42.

University of California.—September 14, 1921. Subject: "Railway Electrification Progress." Speaker: Mr. E. A. Palmer, Westinghouse Electric & Manufacturing Company, San Francisco. Attendance 47.

September 28, 1921. Subject: "Transformers." Speaker Mr. Walter C. Smith, of the General Electric Company. Attendance 40.

Carnegie Institute of Technology.—October 4, 1921. Election of officers as follows: Chairman, Edward A. Brand; Vice-Chairman, William S. Andrews; Secretary, Harold W. Bryan; Treasurer, Allan T. Johnston. Attendance 50.

University of Colorado.—October 6, 1921. Dean Evans spoke on the history, organization and purpose of the American Institute of Electrical Engineers; Professor Du Vall outlined some of the past activities of this Student Branch of the Institute; Professor Coover gave suggestions for the future programs for the Branch. Attendance 38.

Iowa State College.—October 5, 1921. Subject: "The Development of the Caribou Plant of the Great Western Power Company" (located on the Feather River in the Sierra Nevada Mountains). Speaker: Mr. Albert A. Northrop, of the Stone & Webster Co., Boston. The lecture was illustrated by slides and motion pictures. Attendance 135.

University of Kansas.—October 5, 1921. Talks: "Explanation of the A. I. E. E.," by Professor Shaad; introductory talks by Professors Johnson, Newman and Warner. Attendance 77.

University of Michigan.—October 12, 1921. Professor John C. Parker gave a talk in which he stated that the engineer of today is being too much advised to emphasize the social side of the profession and not enough stress is laid upon the fundamentals underlying it. Attendance 55.

University of Notre Dame.—October 10, 1921. Election of officers as follows: Chairman, John D. Fitzgerald; Vice-Chairman, Edward P. Kreimer; Secretary, Walter L. Shilts; Treasurer, Vincent J. Brown. Attendance 37.

Oregon Agricultural College.—September 28. 1921. A film loaned by the General Electric Company was shown, showing the manufacture of Electric Light Sockets. Attendance 45.

Purdue University.—September 20, 1921. Subjects: "Advantages of Belonging to the A. I. E. E." by Professor C. F. Harding; "Different Kinds of Memberships" by Professor D. D. Ewing; short talks by Professor D. L. Curtner and Mr. E. Pugh. Attendance 181.

September 27, 1921. Subject: "The Caribou Hydroelectric Plant of California." Speaker: Mr. Albert A. Northrop, of Stone & Webster Co. Mr. Northrop exhibited a number of lantern slides and four reels of moving pictures, in connection with his address. Attendance 208.

University of Washington.—October 4, 1921. Election of officers as follows: Chairman. Mr. C. Edward Allen; Secretary, Mr. Chas. A. Brokaw. Dr. Magnusson addressed the meeting with a few words of welcome and pointed out to the new student the advantages gained by affiliation with the local branch. He then introduced Mr. Geo. S. Smith, who told of some of his experiences in the engineering field since his graduation in 1916. Attendance 38.

West Virginia University.—September 28, 1921. Election of officers as follows: Chairman, H. Chandler; Vice-Chairman, C. M. Hill; Secretary, W. D. Stump; Treasurer, J. L. Hark. Attendance 25.

Yale University.—October 12, 1921. Social meeting of all members of the Electrical Engineering Department. Professor C. F. Schreiber spoke on the subject of "Evaluating Your Experiences." Short talks were also given by Professors Scott, Turner, Knowlton, Wittig and Warner. Refreshments were served. Attendance 24.

EMPLOYMENT SERVICE BULLETIN

OPPORTUNITIES.—Desirable opportunities for service from responsible sources are announced in this Bulletin, and no charge therefor is made.

MEN AVAILABLE.—Under this heading brief announcements (not more than fifty words) will be published without charge to the members. Announcements will not be repeated except upon request received after a period of three months, during which period names and records will remain in the active files.

NOTE.—Notices for the JOURNAL **should be addressed to EMPLOYMENT SERVICE, 33 West 39th Street, New York, N. Y.,** *the employment clearing house of the Societies constituting the Federated American Engineering Societies, and* **not** *to the A. I. E. E.*

Notices for the JOURNAL are not acknowledged by personal letter, but if received prior to the 16th of the month will appear in the issue of the following month.

All replies to either "Opportunities" or "Services Available" should be addressed to the key number indicated in each case **and forwarded to EMPLOYMENT SERVICE, as above.**

Replies received by the bureau after the position to which they refer has been filled will not be forwarded, and will be held by the bureau for one month only.

Information regarding the notices published is on file in the offices of the member societies of the Federated American Engineering Societies.

POSITIONS OPEN

The United States Civil Service Commission announces an open competitive examination for associate electrical engineer. Vacancies in the Bureau of Mines, Department of the Interior, for duty at Pittsburgh, Pa., at $3000 to $4000 a year, and in positions requiring similar qualifications throughout the United States, at these or higher or lower salaries, will be filled from this examination, unless it is found in the interest of the service to fill any vancancy by reinstatement, transfer or promotion. Applicants should at once apply for Form 2118, stating the title of the examination desired, to the Civil Service Commission, Washington, D. C., the Secretary of the United States Civil Service Board, Customhouse, Boston, Mass., New York, N. Y., New Orleans, La., Honolulu, Hawaii; Post Office, Philadelphia, Pa., Atlanta, Ga., Cincinnati, Ohio, Chicago, Ill., St. Paul, Minn., Seattle, Wash., San Francisco, Calif., Denver, Colo., Old Customhouse, St. Louis, Mo.; Administration Building, Balboa Heights, Canal Zone; or to the Chairman of the Porto Rican Civil Service Commission, San Juan, P. R.

Applications should be properly executed, excluding the medical certificate, and must be filed with the Civil Service Commission, Washington, D. C., with the material required, prior to the hour of closing business on November 15, 1921.

YOUNG ENGINEERS not over 35 years o age for training to handle electrical and me

hanical problems of erection and electrical testing in connection with telephone development in New York City. Location New York City. X-1087.

SALESMAN for a-c. and d-c. motors up to 30 h. p., and high grade electrical machinery. Location, New York City. X-1135.

ELECTICAL and MECHANICAL Constructing Engineering Company, with an established reputation for reliability acquired through many years of successful business experience, desires man to help in estimating and following up the progress of jobs. Preference will be given to a technical graduate who has had successful experience in the electrical contracting business. He must be able to give good references from former employers. Position should be permanent and lead to rapid advancement for man who can make good. X-1155.

ENGINEERS well qualified to take full charge of an office and warehouse, carrying well assorted stock of high-grade steel products, embracing high-speed steels, complete line of tool steels, drill steels, spring steels, machinery steels, etc. Must be thoroughly trustworthy and well recommended. Must be experienced steel salesman, as well as practical men, thoroughly familiar with modern methods of heat treating and qualified to act as demonstrators. In other words, they should be conversant with the quality steel business and should be ideal salesmen in every sense of the word. Would also be desirable if those men understood conditions peculiar to Eastern markets. Application by letter outlining in detail experiences and references, together with idea of salary or drawing account, rate of commission, length of contract, etc. Location, Far East, China, and Japan. X-1166.

SALES ENGINEER for a concern supplying steam for the operation of dynamo engines, pumps, refrigerating equipment, heating apparatus, etc. Practical experience in connection with the operation of dynamo engines, and pumps in isolated plants such as office buildings, hotels, etc. Must have had experience in selling. Location, New York City. X-1168.

SALESMAN to sell electrical safety switches. To take charge of a district office and supervise the work of two other salesmen. Should have technical education or thorough knowledge of the use of electricity, and where and why switches are required. It is our intention to develop a model district office, utilizing the principle of scientific management which has proved very successful in handling our production during the last five years. Under this plan we would have an Engineering and a planning department and district sales manager would have his work scheduled as well as that of the salsemen working for him. Location, Michigan. X-1176.

DRAFTSMAN with engineering degree, must be thorough in physics and well experienced in chemistry and light, also to have knowledge of electricity for the purpose of designing mechanical and electrical details. Man having experience of waters and gases preferred. Must be highly recommended for confidence. No other than those who can well qualify need apply. Location, New Jersey. X-1211.

INSTRUCTOR preferably with previous teaching experience in theoretical mechanics and mechanics of materials, for state university. Location, South. X-1214.

EQUIPMENT ENGINEER. Facilities layout, etc., of telephone central office equipment with large operating company. Give details of past experience, age and present and expected salary, etc. Location Ill. X-1220.

SALES ENGINEERS by company selling heat insulating materials on national scale. Present openings New York and Chicago. Splendid opportunity for progressive men with some previous selling experience. X-1215.

GRADUATE ELECTRICAL ENGINEER with two or three years experience for research work on electric meters. X-1233.

ENERGETIC ELECTRICAL man with executive, estimating and new business abilities, to take complete management of a going electrical contracting and repair business. May invest if desired. Location Brooklyn, N. Y. Application by letter. X-1241.

PHYSICIST experienced in physical chemistry and thermochemistry. At least three years research experience. Location New Jersey. X-862.

MEN AVAILABLE

TECHNICAL GRADUATE in electrical engineering, thoroughly grounded in chemistry, desires position with opportunity for advancement in Southeastern Ohio, but would gladly consider other locations. Unmarried and can furnish good references. E-3012.

MECHANICAL-ELECTRICAL ENGINEER Technical graduate, G. E. Test. Age 37, fourteen years practical experience in the design, construction and operation of steam, hydroelectric and factory plants in responsible charge as, chief engineer, engineer of works and general superintendent. Desires position with room for advancement. E-3013.

ELECTRICAL ENGINEER—B. S. Degree, age 23, single. One year's experience as foreman electrician in manufacturing plant. Desires position in electrical and mechanical maintenance. E-3014.

HEATING DEVICE ENGINEER—Electrical engineer, age 27, married, experienced in electrical heating devices, is looking for opening in Chicago. Small company preferred. Have had experience with large manufacturer of above appliances. Available upon two weeks' notice. E-3015.

ELECTRICAL ENGINEERING GRADUATE of a four-year recognized technical school desires a position with an electrical concern. 1921 graduate, age 24, single. Position in power plant or substation of power company or electrical railway accepted if there is a chance for advancement. Reference supplied if desired. Employed at present but available on short notice. Location immaterial. E-3016.

TECHNICAL GRADUATE of Electrical Engineering course, '20, age 26, unmarried, four years experience in sales work. Desires position as salesman with a well established company. Prefer to sell electrical supplies. Will go anywhere. Initial salary immaterial. Available on short notice. E-3017.

ELECTRICAL ENGINEER, age 20, college graduate, ten weeks experience, General Electric Company's testing department. Desires position with engineering, manufacturing, or light and power company, where opportunity for advancement is presented. Location, New York City or vicinity preferred, but am willing to go West if necessary. Available immediately. E-3018.

ELECTRICAL ENGINEER—12 years in research and development work on motor control for general motor applications, including traction, electric automobiles and trucks. Age 33; married; graduate in electrical engineering. Member A. I. E. E. and S. A. E. E-3019.

MANAGER OR SUPERINTENDENT, electrical and mechanical engineer, executive ability, age 38, married, thoroughly trained, wishes change and opportunity for advancement. First class experience in manufacturing, installation of electrical apparatus, electric railway track and equipment construction and maintenance, and general management of railways. Good at dealing with labor and public relations. At present located in Canada. E-3020.

ELECTRICAL ENGINEER, available for domestic or foreign service. Graduate student course Westinghouse Company. Experienced in design of central stations and transmission lines. Member A. I. E. E. Age 31, married. Additional information upon request. E-3021.

ELECTRICAL ENGINEER, university graduate, age 27 years. Three years experience at the plants of the General Electric Company and two years experience in the construction and layout of power houses and substations for rubber plants, glass works steel mills and coal mines. E-3022.

ELECTRICAL GRADUATE—Assoc. A. I. E. E. Competent, age 30. Five years maintenance foreman; d-c. and a-c. apparatus; four years laboratory tests; one year New York Edison tests. Desires position in vicinity of New York, offering an opportunity for advancement. Good references furnished. Available at once. E-3023.

FIRST CLASS ELECTRICIAN—Age 31, married. Maintenance motor and generator work and factory installation, 13 years experience. Available immediately. Northern New York preferred. Associate A. I. E. E. E-3024.

ELECTRICAL DISTRIBUTION ENGINEER, technical graduate, age 28, married. Experience includes G. E. test course, construction and operation of generating stations, construction and design of overhead lines. Desires place as assistant to electrical engineer or assistant to manager of progressive central station company. Responsibility wanted. E-3025.

POWER AND MECHANICAL ENGINEER, technical graduate, B. S. and M. E., age 30, eight years experience along broad lines, machine shop, metallurgy, chemical manufacturing, sugar engineering, industrial and power plant practise, operation, design, layout, calculations, heating, distribution of steam, water, etc. Has business and executive ability. Desires responsible position. E-3026.

ELECTRICAL ENGINEER, technical graduate, age 26. Three years experience in electrical drafting and layout. Experience in sales engineering. Wishes position as electrical or sales engineer. Would consider establishing agency. Single. Location preferred New York City. E-3027.

GRADUATE ELECTRICAL ENGINEER, Case 1920, age 23. Westinghouse graduate student course, eight months engineering experience on industrial motors at Westinghouse. At present on substation construction. Desires position in engineering or construction department of progressive power company. Middle west or eastern location preferred. Available on short notice. E-3028.

MOTORS AND MOTOR-DRIVEN MACHINERY are my specialty. Five years with large motor manufacturer and four years with well-know manufacturer of electrically driven machinery as head of department. Practical engineer with unusual theoretical knowledge, B. S. and E. E. degrees. University of Illinois. Some teaching experience. Consulting or designing accepted. E-3029.

GOOD, LIVE, WIDE AWAKE ELECTRICAL ENGINEER—Technical graduate, desires position requiring initiative, tact, and engineering ability. Four years General Electric Laboratory—Tests—Radio and Sales. Location preferred Middlewest. Available on short notice. E-3030.

ELECTRICAL ENGINEER—Age 36, married Ten years overhead and underground construction. Three years sales engineer, high-tension distribution specialties. Three years manager engineering sales electrical supply house. Circumstances render it necessary to make Chicago permanent residence. Desire to represent electrical manufacturer on salary and commission basis. Exceptional references. E-3031.

ELECTRICAL ENGINEER—Age 34, single, technical graduate, two years General Electric Company. Testing Department, two years public utility company, five years research work on automotive equipment; desires position as experimental or research engineer. Associate A. I. E. E. and American Mathematical Society. E-3032.

TECHNICAL STUDENT—Age 23, desires position with electrical duties, in laboratory or office of electrical engineering concern; 5th year student in E. E. at Cooper Union Night. Four years clerical, three years practical experience. E-3033.

GRADUATE MECHANICAL AND ELECTRICAL ENGINEER, export and import

manager, age 38, member American Chamber of Commerce, Paris-London, six years in far East, seven languages, open for new connection. E-3034.

ENGINEER-EXECUTIVE of eighteen years experience manufacturing, designing, sales engineering on motors, controllers, batteries, cranes and hoists; seven years college training; broad, resourceful, energetic, agreeable. Salary $5700. Five years present responsible position; ten years with another well-known engineering force. Seeks position factory manager, chief engineer or sales engineer. E-3035.

ELECTRICAL ENGINEER—Age 35, technical graduate, fourteen years experience in industrial and public service power plants in construction, maintenance and operation, desires position as manager of electric plant, or electrical engineer for industrial plant. Available on short notice. Western states preferred. Assoc. A. I. E. E. E-3036.

ELECTRICAL ENGINEER—Technical graduate, age 34, married; Assoc. A. I. E. E., ten years experience in construction, maintenance, and testing; desires position with future; can handle men and deal with public successfully. Location U. S. Available immediately. E-3037.

ELECTRICAL-MECHANICAL ENGINEER—Technical graduate, broad practical engineering experience. Ten years experience in power plant, substation and electrical construction work. This includes estimating, design, specifications, purchasing and supervision of drafting and erection work. Well versed in problems in connection with power plant economics and electric railways. Available on short notice. E-3038.

ELECTRICAL ENGINEER—Technical graduate, ten years experience, testing, operating, designing, construction and managing electrical utilities. Can furnish good references. Am a strong executive and good organizer. Present salary $3000. Age 31. Married. Mem. A. I. E. E. E-3039.

ELECTRICAL - MECHANICAL INDUSTRIAL AND DESIGNING ENGINEER—Age 42; university graduate; able executive. Fifteen years' shop, office and field experience, in estimating, appraisal, engineering economics, design, construction and equipment of power plants, substations and factories. Salary in proportion to responsibilities. E-3040.

ELECTRICAL ENGINEER—Technical graduate, Associate A. I. E. E., with nine years experience in design, construction and operation of central stations, and power applications to railways and mining properties, desires to make connection with construction or operating company or consulting engineer engaged in above lines. E-3041.

ELECTRICAL ENGINEER, experienced in central station industry, experimental engineering laboratory, and teacher of electrical engineering. Desires to connect with concern requiring the services of a capable, energetic, and conscientious man. Salary requirements moderate. Age twenty-eight years. Married. E-3042.

HYDROELECTRIC SUPERINTENDENT—Age 31, married, fourteen years excellent practical experience on construction operation and maintenance of power systems, seven years in foreign service of United States Government, can handle men and produce results. At present holding responsible position with large power company on Pacific Coast. Desires to locate permanently in New York State. Associate A. I. E. E. E-3043.

SALES ENGINEER—Age 35, married. Ten years exceptional sales record calling on electrical jobbing, contractor and industrial trade in central West, South and parts of East. Six years present connection manufacturing plant. Familiar with modern factory methods and production, machine design, foundry practise and die and pattern design. Also six years design manufacturing and operation of telephone equipment. Available 30 days. Present location Ohio. E-3044.

GRADUATE ELECTRICAL AND MECHANICAL ENGINEER-Married, age 29, desire position where my experience will fit in, four years with Westinghouse Electric & Manufacturing Company, assembling, testing, designing and engineering. Two years with steel company, construction, power house operating, trouble and operating both in the mill and office switchboard designer and sales engineer. E-3045.

EXECUTIVE—Publicity and advertising, sales promotion, technical journalist, progressive, successful writing experience covering newspaper, magazine and industrial fields. Formerly special writer on leading New York business daily on business news. Have been assistant advertising manager of the Edison Storage Battery Company, and for more than two years assistant editor of Science & Invention. Desire connection where initiative and executive ability assure position limited only by my own capabilities. Salary to start $2500 year. New York or vicinity. E-3046.

TECHNICAL GRADUATE—B. S. 1920. Student A. I. E. E., age 24, unmarried, desires position as fire inspector with some insurance inspection bureau. Fifteen months experience rating under the Dean Schedule. Good references, now employed; available about January 1st. E-3047.

INDUSTRIAL ENGINEER—Now electrical engineer of works with 4000 lamps, 1200 motors, 120 traveling cranes, 10 locomotive cranes, power plant with alternating and continuous-current equipments, etc. Mem. Am. Soc. M. E., A. I. E. E., A. E. S., I. E. S., I. & S. E. E., A. A. A. S., etc. Age 34; salary desired $6000. E-3048.

ELECTRICAL ENGINEER, age 30. Single, A. I. E. E., A. S. M. E. and A. I. & S. E. E. Six years mining and steel mills electrical work, one year estimating and designing, one year purchasing electrical equipment. Two years foreign electrical construction. Available two weeks; location anywhere. E-3049.

ELECTRICAL ENGINEER—Assoc. A. I. E. E., age 38, married. Fifteen years electrical engineering experience. Last five years engineer in charge high-tension distribution, power plant design and construction. Heavy electric traction. Desires connection with some engineering concern in same capacity or as consulting engineer with some municipality. Salary $3000. E-3050.

SUPERINTENDENT—Mechanical and electrical, power plant construction preferred. Can qualify as plant or maintenance engineer for manufacturing or chemical concerns. Fifteen years experience, four years hydroelectric construction, maintenance and operation. University graduate, age 35. Present salary $350. Would consider taking up sales work at some sacrifice in salary to start. E-3051.

ELECTRICAL ENGINEER—B. S. E. E. degree; Assoc. A. I. E. E., married, age 35. Ten years varied experience; three years appraisal of electrical properties; one year motor repair; three years construction, inspection, shop and test; three years construction, installation, maintenance and operation as chief electrician. Desires position of taking charge of electrical department of large industrial plant or acting as assistant to consulting electrical engineer. Salary $3000. Location, Pacific slope or north-west. Available February 1, 1922. E-3052.

ENGINEER—Jr. A. S. M. E., Assoc. A. I. E. E., desires position construction work, maintenance or operation. Experience with a-c. and d-c. twelve years practical. At present superintendent construction department of large electric company. E-3053.

ELECTRICAL ENGINEER—Graduate 1921, age 26, single, desires position with hydroelectric or power transmission construction company doing work in foreign country. South America or Mexico preferred. Available at once. E-3054.

ELECTRICAL ENGINEER—Age 34, married, university education, desires position with company offering opportunity for advancement. Ten years experience in charge of central station operation, including high-tension substation, conduit construction and cable installation, overhead distribution and plant operation. Can furnish references. Salary $4000. Available on reasonable notice. E-3055.

ELECTRICAL ENGINEER—Age 27, married, technical education, seeks connection with manufacturing concern as head of electrical department. Six years experience installation, operation and maintenance of power and electrical equipment, including one year experimental and development work in electrical laboratory. Associate A. I. E. E. Executive ability. Location immaterial. Available immediately. E-3056.

EXECUTIVE OR CONSULTING ENGINEER—Very broad experience in electrical field including practically all phases of industrial electrical engineering such as power plant design, motor layouts, lighting installations, transmission and distribution system, specifications, estimates, appraisals, reports, etc. Six years experience in electrical manufacturing companies, twelve years in responsible charge of the industrial electrical engineering work of one of the largest engineering firms of the country. Open for engagement January 1st as executive or consulting engineer. E-3057.

ELECTRICAL ENGINEERING GRADUATE, Assoc. A. I. E. E. Experience includes general wiring, telephone exchange installation and maintenance, four years in motion picture projection field. Desires position with concern in Cleveland or vicinity. Initial salary secondary. Work must be attractive and offer advancement and future in recognition of hard work. Age 24. Present salary $2600. E-3058.

EXECUTIVE — CONSTRUCTION ENGINEER (ELECTRICAL)—Age 30. Will take entire charge of construction. Thoroughly familiar with design, selection, operation and installation of radio equipment for marine and coastal stations. Experienced layout and construction complete stations, including erection masts, antenna and buildings. Also installation switchboards, transmitters and auxiliaries. Interviews New York and vicinity. E-3059.

ELECTRICAL ENGINEER—B. S. degree 1919, age 23, single, desires position in the East. Energetic and hard worker, with two years steel mill experience on construction and maintenance. Also design work on a-c. and d-c. magnetic control. Available on moderate notice. E-3060.

RADIO ENGINEER, technical graduate; age 34, with twelve years experience in design construction and operation of high power radio stations and the installation of various types of receiving apparatus, is open for position with radio concern or with firm where experience with high power high frequency may be useful. E-3061.

UTILITY MANAGER AND ENGINEER. Broad experience in construction and operation of all classes of utilities, including refreigeration, desires similar position or connection with a manufacturing company to work into sales department. Successful in the sale of securities and power. E-3062.

ELECTRICAL ENGINEER, technical graduate; age 30; married. Desires position with large industrial plant or big mining company. Three years with Westinghouse Co. in their main shop and service department. Last six years engineer in full charge of installation and repair in iron mines in New Jersey. Location, Atlantic Seaboard. E-3063.

GRADUATE ELECTRICAL ENGINEER, single; age 25. Desires situation with central station, consulting engineer or manufacturing company. Four years experience. Electrical testing, factory accounting, army officer, public utility, appraisal and construction. Opportunity not immediate salary main consideration. Available at once. E-3064.

MEMBERSHIP — Applications, Elections, Transfers, Etc.

ASSOCIATES ELECTED OCTOBER 14, 1921

AINSWORTH, STUART, Assistant Engineer, Peruvian Corporation, Ferrocarril del Sur., Arequipa, Peru, S. A.

ALONZO, FRANCISCO F., Electrical Tester, Westinghouse Elec. & Mfg. Co.; res., 114 S. Negley Ave., Pittsburgh, Pa.

ALSOBROOK, HENRY L., Asst. Repeater Chief, Western Union Telegraph Co.; res., 2108 Green St., Columbia, S. C.

ASHMORE, JOSEPH, Electrical Engineer Surveyor, British Engine Boiler & Electrical Insurance Co., Ltd.; res., 28 Fulford St., Old Trafford, Manchester, England.

AUBERT, FRANCIS, Asst. Electrical Engineer, Distribution Dept., Mexican Light & Power Co., 7a de Durango 118, Mexico City, Mex.

BARON, ROBERTO J. B., 13 Rua Paulino Affonso, Petropolis, Est. D. Rio, Brazil, S. A.

BATES, EARL J., Electrical Engineer, Research Dept., National Cash Register Co.; res., 515 Albany St., Dayton, Ohio.

*BAYLE, RUSSELL M., Service Engineer, Westinghouse Elec. & Mfg. Co., E. Pittsburgh; res., 1219 Mill St., Wilkinsburg, Pa.

BELL, TRICE MORTON, Engineer, General Electric Company; res., 417 Union St., Schenectady, N. Y.

BOND, THOMAS KIRK, Civil Engineer, Utah Consolidated Mining Company, Tooele City, Utah.

BOOTH, JOHN A., Transformer Engineer, British Thomson-Houston Co., Ltd., Rugby, England.

BUGEJA, CHARLES, Tester, Electrical Construction Dept., Brooklyn Edison Co., 569 Fulton St., Brooklyn, N. Y.

BUSH, CLARENCE R., Electrical Construction Engineer, Central Illinois Light Co.; res., 1033 North St., Peoria, Ill.

BUTLER, V. DELL, Foreman, Power Plant, Portland Railway, Light & Power Company, Bull Run, Oregon.

CASTRO, JORGE E., Superintendent, Testing Meters, Mexican Light & Power Co., Gante St. No. 20, Mexico City, Mex.

COFFIN, CHARLES D., Draftsman, New England Tel. & Tel. Co., Lowell; res., Tyngsboro, Mass.

COLABAWALA, JEHANGIR R., Executive Engineer, The Parbati Hydro-Electric Irrigation & Water Works Project, Morar, C. India.

COX, ASA WALTER, Electric Foreman, Carnegie Steel Company, McDonald; res., 2712 Alma Ave., Youngstown, Ohio.

CRAIG, ALBERT G., Assistant Engineer, United Electric Light & Power Co., 130 E. 15th St.; res., Apt. D1, 2440 Webb Ave., New York, N. Y.

CUNNINGHAM, JOHN T., Student, Heffley Institute; res., 136 Nostrand Ave., Brooklyn, N. Y.

DAVISON, GEORGE E., Asst. Engineer, Virginia Railway and Power Co.; res., 215 So. Mulberry St., Richmond, Va.

DE LOACHE, ROBERT LEE, Switchboard Designer, Westinghouse Elec. & Mfg. Co., 56 Magnolia St., Atlanta, Ga.

EGEE, JOSEPH W., Sales Engineer, Electric Appliance Company, New Orleans, La.; res., 21 Adams St., Montgomery, Ala.

ELIESON, EDWIN E., Electrician, American Smelting & Refining Co., 327 Vine St., Murray, Utah.

FRANKEL, CHARLES B., Assistant Engineer, Underground Extensions, Commonwealth Edison Co., 72 W. Adams St., Chicago, Ill.

*FREUCHEN, THORD H., Electrical Designer, Braden Copper Co., Rancagua, Chile, S. A.

FRIEND, HENRY M., Asst. Electrical Inspector, Engineering Material, U. S. Navy, 44 Court St., Brooklyn; res., 316 W. 97th St., New York, N. Y.

FUKAMI, GEN-ICHIRO, Electrical Engineer, Mitsubishi Shipbuilding Co., 120 Broadway, New York, N. Y.

GARDNER, MURRAY F., Testing Laboratory, American Steel & Wire Co., Worcester, Mass.; res., 508 N. Capitol Ave., Lansing, Mich.

GIBBON, THOMAS HUTCHINSON, Electrical Engineer, Engineering Dept., Canadian General Electric Co.; res., 49 Gilmour Ave. Toronto, Ont.

GILDER, THOMAS N., Asst. Engineer, Valuation Dept., Portland Railway, Light & Power Co., Electric Bldg., Portland, Ore.

GILL, CLARENCE RHODES, Electrician & Student, Dynamo Laboratory, University of Wisconsin, Madison, Wis; res., 5708 Harper Ave., Chicago, Ill.

GONZALEZ, ARTURO, JR., Superintendent, District No. 2, Porto Rico Railway, Light & Power Co., San Juan, P. R.

GOODWIN, RALPH J., Superintendent & Electrical Engineer, Municipal Electric Plant, Dothan, Ala.

GRUNER, RAYMOND W., Sales Dept., Allis-Chalmers Mfg. Co., Milwaukee; res., 5031 National Ave., West Allis, Wis.

GUIDONI, ALESSANDRO, Lieut-Col., Air Attache, Italian Embassy, 1400 New Hampshire Ave., Washington, D. C.

HALDEMAN, THEODORE T., Superintendent of Public Works, Borough of Chatham, Chatham, N. J.

HALL, JACK H., E. E., Lihue Plantation Co., Ltd., Lihue, Kauai, T. H.

*HALPERIN, HERMAN, Commonwealth Edison Co., 72 W. Adams St., Chicago, Ill.

HARROP, EVERETT T., Field Engineer, New England Telephone & Telegraph Co.; res., 30 Crystal St., Worcester, Mass.

HATCH, PHILIP H., Student Engineer, General Electric Company, Schenectady; res., 425 Pelham Manor Road, Pelham Manor, N. Y.

HAUSER, ALBERTO, Superintendent of Connections & Electrical Control Depts., Mexican Light & Power Co., Mexico City, Mex.

HEIMBACH, ELBERT B., Electrical Engineer, American Appraisal Co.; res., 502 35th St., Milwaukee, Wis.

HICKOCK, HAROLD CLARK, Engineer, General Engineering Dept., Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.

HUANG, YOUNG-TSIEH, Student-Engineer, Bell Telephone Company of Pa., Philadelphia, Pa.

INOUE, FUKUTANE, Chief Engineer, Hanshin Express Electric Railway Co., Osaka, Japan; Mitsui & Co., 65 Broadway, New York, N. Y.

JEFFERSON, WILLIAM E., Engineering Dept., Maritime Tel. & Tel. Co., Ltd., Halifax, N. S.

JOHNSON, CARL W. D., Electrical Engineer, Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.

*KEEFE, WALTER L., Electrician, Lord Electric Co., 112 Water St.; res., 8 Irving St., Boston, Mass.

KOMATSU, MOHACHI, Engineer, Patent Dept., Tokyo Electric Co., Kawasaki, Japan.

KROGH, GUNNAR E., Engineering Office, Elektrodrift, Sjofartsbygingen 450, Kristiania, Norway.

KUROYANAGI, KENKICHI, Electrical Engineer, Oi Works, I. G. R., Oimachi, Tokyo, Japan.

LANE, DAVID M., Assistant Engineer, William Barclay Parsons, 84 Pine St., New York, N. Y.; res., 584 Jersey Ave., Jersey City, N. J.

LAVARELLO M, JUAN J., Electrical Sub-Foreman, Coya Power House, Braden Copper Co., Rancagua, Chile, S. A.

LEADER, ALVA A., Electrical Contractor, Kingman, Ariz.

LEIGHTON, HAROLD W., Radio Electrician, & Laboratorian, Navy Yard, Boston; res., 3 Quincy St., Somerville, Mass.

*LEROUX, HERMANUS S., Bethulie, O. F. S, So. Africa.

MACIAS, CARLOS, Manager & Engineer of Electromotor, S. A., Isabel La Catolica 43, Mexico, D. F.

MACKAY, ST. CLAIR, Paymaster, L. K. Comstock & Co., Inc., 21 E. 40th St., New York, N. Y.

MARSHALL, JOSEPH H., 509 East 77th St., New York, N. Y.

MATFL, EMIL, Electrical Operator, Edison Electric Illuminating Company, Boston, Mass.

*MATTHEWS, THOMAS, Instructor, University of North Dakota, Grand Forks, N. Dakota.

McINNES, EDWARD H., Resident Engineer, Western Electric Company, Wellington, N. Z.

McLAUGHLIN, GEORGE S., Transitman & Inspector, City Engineer's Office; res., 145 S. Garfield Ave., Pocatello, Idaho.

MERCER, GEORGE G., School of Electrical Engineering, Purdue University, La Fayette, Ind.

METLIE, PAUL J., Testing Dept., Allis-Chalmers Co.; res., 5031 National Ave., West Allis, Wis.

MITCHELL, CHARLES T., Municipal Electrician, Municipal Hall, Kerrisdale; res., 2033 Trafalgar Road, Vancouver, B. C.

MORISHIMA, TEIICHI, Vice-Chief of Design Dept., Hitachi Engineering Works, Sukegawa Ibarakiken, Japan.

MULLER, KARL E., Dr., Electrical Engineer, Mexican Light & Power Co.; res., 4a, Durango 59, Mexico, D. F., Mex.

NARAYANAN, MANAKAL S. I. A., Assistant Engineer, Public Works Dept., Pyinmana, Burma, India.

PAOLINO, SERAFINO, Elec. Draftsman, Pacific Gas & Electric Co., San Francisco; res., Tiburon, Marin County, Calif.

PEEPLES, RICHARD G., Electrical & Mechanical Engineer, 136 N. Central Ave., Phoenix, Ariz.

PETERSEN, JOHN D., Electrical Engineer, Maxwell Motor Co., Inc., Oakland Ave., Detroit, Mich.

PINELES, SETH M., Engineer, Westinghouse Electric & Mfg. Co., E. Pittsburgh; res., 7111 Reynold St., Pittsburgh, Pa.

PIOCH, FRANK H., Chief Electrician, Glogora Coal Co., Montcoal, W. Va.

POTTS, HAROLD R., Switchboard Operator, New York Edison Co., 98 Vandam St., New York; res., 280 Rutledge St., Brooklyn, N. Y.

QUINLAN, JOSEPH M., Salesman (Motors & Plant Equipment), Hawaiian Electric Co., Ltd., King St., Honolulu, T. H.

RAMINEZ, JAVIER P., Draftsman, Mexican Light & Power Company, Mexico City, Mex.

REES, EDWARD H., Electrical Engineer, Illinois Glass Co., Alton, Ill.

REID, IRL C., Receiving Engineer, Radio Corporation of America, Koko Head, Oahu, T. H.

ROSS, FRANK W., Asst. Cost Engineer, Lehigh Power Securities Corp.; res., 323 N. 8th St., Allentown, Pa.

SCHANZ, JOHN, JR., Student of Electrical Engineering; res., 230 E. 18th St., New York, N. Y.

SCHEINBEIM, HYMAN, 1517 Charlotte St., New York, N. Y.
SCHOLZ, HERBERT J., Lighting Engineering Dept., General Electric Company, Schenectady, N. Y.
SMART, LEE ROY, Service Inspector, American Tel. & Tel. Co., 311 W. Washington St., Chicago, Ill.
SMITH, CHARLES H., Electrical Contractor & Engineer, 78 2nd St., San Francisco; res., Mill Valley, Calif.
SMITH, GEORGE M., Valuation Engineer, Murrie & Co., 74 Broadway, New York, N. Y.; res., 310 Hillside Ave., Newark, N. J.
SMITH, WALDORF ASTOR, Rayville, Louisiana.
SOLIS, GREGORIO, Inspector of Local Distribution, Mexican Light & Power Co., Sucursal, B-Mexico, D. F.
SOUJA, ODILON E. do A., Chief of Electrical Construction Dept., Sao Paulo Tramway, Light & Power Co.; res., Avenida Turmalina 7 (Acelimacao), S. Paulo, Brazil, S. A.
SPENCER, THOMAS G., Asst. Supt., Cable Plant Western Electric Co., Ltd., North Woolwich, London, S. E., Eng.
STECHER, LEWIS J., Lieutenant Commander, U. S. S. Wyoming; New York, N. Y. res., 16 Union Ave., Schenectady, N. Y.
SUTTON, PORTER O., President & Engineer, Norfolk Electric Mfg. Co., 217 Cumberland St., Norfolk, Va.
TAKAO, NAOSABURO, Director, Hitachi Engineering Works, Sukegawa, Ibarakiken, Japan.
TAMAGAWA, HISAO, Chief Electrical Engineer, Electrical Dept., Hitachi Mine, Ibaraki-ken, Japan.
TAO, FENG-SHAN, Student Engineer, Bell Telephone Company of Pennsylvania; res., 1830 S. Logan Square, Philadelphia, Pa.
THOMPSON, LAWRENCE F., Asst. Construction Engineer, The Mountain States Tel. & Tel. Co., Salt Lake City, Utah.
TUNISON, LESTER E., Substation Operator, Southern California Edison Co., res., 1606 Ingraham St., Los Angeles, Cal.
WARD, OSCAR P., Electrician, Paintsville, Ky.
WARD, RICHARD H., Manager, Ringsdorff-Werke, A. G., 521 W. 23rd St., New York, N. Y.
WEIR, WILLIAM S., Engineer-in-Charge Power Station, Glasgow Corporation Tramways; res., 8 Scotia St., Glasgow, Scotland.
WILLIAMS, ALEC D., Electrical Engineer, The Broken Hill Proprietary Co., Ltd., Broken Hill, N. S. W., Aus.
WILLIAMS, H. L., Manager, Evanston Electric Light Co., Evanston, Wyoming.
WILLIAMS, ISABELLE CONKLING, Telephone Engineer, Western Electric Co., 463 West St., New York; res., 28 Covert Place, Flushing, N. Y.
YOKOTA, CHIAKI, Charge of Switchgear Design Dept., Hitachi Engineering Works, Sukegawa, Ibarakiken, Japan.
YOSHIDA, GENZO, Commercial Electrical Engineer, Engineering Dept., Mitsui & Co., 65 Broadway, New York, N. Y.

Total 106.

*Former enrolled students.

ASSOCIATES REELECTED OCTOBER 14, 1921

FAUCETT, FRANK FIELDING, Chief Engineer, Enterprise Electric Company, 521 1st Ave., Spokane, Wash.; Joseph, Ore.
MORGAN, THEODORE BLACKWELL, Asst. Superintendent, Southern Division, Public Service Electric Co.; res., 18N. Eastfield Ave., Trenton, N. J.
WADE, MARK LEIGHTON, 2867 Graveley St., Vancouver, B. C.

MEMBER REELECTED OCTOBER 14, 1921

FISHER, HARMON FRANCIS, Liguefaction Engineer, U. S. Bureau of Mines, 2116 Interior Bldg., Washington, D. C.

FELLOW REELECTED OCTOBER 14, 1921

PIKLER, HENRY, Managing Director, Teudloff-Dittrich Mfg. Co.; res., 30 Ulloi-ut, Budapest, Hungary.

MEMBERS ELECTED OCTOBER 14, 1921

DUNMIRE, RUSSELL P., Commerical Engineer, Westinghouse Elec. & Mfg. Co., Union Bank Bldg., Pittsburgh; res., Irwin, Pa.
GOULD, HAROLD M., Electrical Engineer, Dept. of Street Railways, Murphy Bldg., Detroit, Mich.
KILLEBREW, EMMET S., President, Albany Electric Co., 126 Court Ave., Albany, Ga.
KUBACH, WILLIAM L., Electrical Engineer, National Lamp Works of G. E. Co., Nela Park, Cleveland, Ohio.
PENN, MARION, Plant Engineer, Public Service Electric Company of New Jersey, Newark; res., 35 Elmwood Place, Elizabeth, N. J.
SMITH, LEON E., Commercial Engineer, General Electric Co., W. Lynn, Mass.
VAL DAVIES, ARTHUR E., Asst. City Electrical Engineer, Corporation of the City of Cape Town, Dock Road Power Station, Cape Town, S. Africa.

TRANSFERRED TO GRADE OF MEMBER OCTOBER 14, 1921

BRUEGGEMAN, FRANK, Asst. Mechanical & Electrical Engineer, South Park Commissioners, Chicago, Ill.
CHRISTIANSEN, KAY C., Electrical Engineer & Supt. of Elec. Construction, Phoenix Utility Co., Hazleton, Pa.
COLVIN, C. W., Asst. Appraiser & Chief Engineer, Appraisal Dept., British Columbia Electric Railway Co., Ltd., Vancouver, B. C.
CONDON, EDWARD J., President, Condon Engineering Co., Chicago, Ill.
CURTIS, ALFRED S., Telephone Engineer, Western Electric Co., New York, N. Y.
DAVIDSON, JOHN, JR., Telephone Engineer, American Telephone & Telegraph Co., New York, N. Y.
DEMAREST, CHARLES S., Electrical Engineer, American Telephone & Telegraph Co., New York, N. Y.
FAIRLEY, G. E. A., Engineer, Buildings and Grounds, Carnegie Institute of Technology, Pittsburgh, Pa.
FIELD, CROSBY, Engineering Manager, National Aniline & Chemical Co., Inc., New York, N. Y.
HALL, GERALD R., Engineer, Apparatus Sales Dept., Canadian General Electric Co., Toronto, Ont.
HAMDI, ABDULLAH F., General Foreman, Test Dept., New York Edison Co., New York, N. Y.
KITTREDGE, CARLYLE, Chief Engineer, Michigan State Telephone Co., Detroit, Mich.
LYTHGOE, JOSEPH, City Electrical Engineer, Christchurch, New Zealand.
MALTHA, GERARD S., Chief Designing & Estimating Engineer, Ebro Irrigation & Power Co., Barcelona, Spain.
MANVEL, FREDERIC I., Installation Engineer, General Electric Co., Pittsfield, Mass.
MORGAN, FRED, Electrical Engineer, Sessions Engineering Co., Chicago, Ill.
NEWLIN, EARL M., Engineer, Superpower Survey, U. S. Geological Survey, New York, N. Y.
PAGE, ROY, General Superintendent, Nebraska Power Co., Omaha, Nebr.
PARSONS, OLIN D., Telephone Engineer, Western Electric Co., New York, N. Y.
PLUMB, HYLON T., Local Engineer, General Electric Co., Salt Lake City, Utah.
PROEBSTEL, D. W., Asst. Engineer, Portland Railway, Light & Power Co., Portland, Ore.
RAKESTRAW, CLAUDE N., Supt. of Lines, Cleveland Electric Illuminating Co., Cleveland, O.
SUTHERLAND, WILLIAM F., Designing Engineer, Toronto Hydro-Electric System, Toronto, Ont.
WARWICK, JOHN F., Engineer, Georgia Railway & Power Co., Atlanta, Ga.
WELLER, CLIFFORD T., Engineer, Gen. Engineering Laboratory, General Electric Co., Schenectady, N. Y.
WORK, WILLIAM R., Prof. of Elec. Engineering Carnegie Institute of Technology, Pittsburgh Pa.

RECOMMENDED FOR TRANSFER

The Board of Examiners, at its meeting held September 30, 1921, recommended the following members of the Institute for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the Secretary.

To Grade of Fellow

GILL, LESTER W., Professor of Electrical Engineering, University of British Columbia; Consulting Engineer; Vancouver, B. C.
GRACE, SERGIUS P., Engineer on Foreign Wire Relations, American Telephone & Telegraph Co., New York, N. Y.

To Grade of Member

CLARK, JAMES C., Associated Professor Electrical Engineering, Stanford University, Stanford University, Calif.
FITZGERALD, THOMAS W., Professor of Electrical Engineering, Head of Department Georgia School of Technology, Atlanta, Ga.
HANSON, C. F., Director of Electrical Research Habirshaw Electric Cable Co., Yonkers, N. Y.
MORGAN, THEODORE B., Asst. Supt., Southern Division, Public Service Electric Co., Trenton, N. J.
MUIRHEAD, JAMES, Government Inspector of Electrical Energy, Province of British Columbia, Vancouver, B. C.
PERTSCH, JOHN G., JR., Assistant Professor of Electrical Engineering, Cornell University, Ithaca, N. Y.
SCHARNBERG, HERMAN J. B., General Superintendent, Palma Soriana Sugar Co., Oriente, Cuba.
WHITEHURST, ROLAND, Manager, Washington Branch, Electric Storage Battery Co., Washington, D. C.

APPLICATIONS FOR ELECTION

Applications have been received by the Secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a higher grade than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the Secretary before November 30, 1921.

Amstutz, J. Oscar, New York, N. Y.
Ard, Lignon B., New York, N. Y.
Baker, Charles L., Green Bay Wis.
Bang, Claus, Three Rivers, Que.
Barrer, Glen A., Chicago, Ill.
Barton, Rensselaer G., Seattle, Wash.
Bibber, Harold W., Cambridge, Mass.
Bisdee, Colin E., Schenectady, N. Y.
Cooper, Herbert W., Worcester, Mass.
Cronstedt, Harry G., New York, N. Y.
Crooke, Roscoe J., (Member), Seattle, Wash.
Daymude, Earl L., Seattle, Wash.
De Chesne, Herbert E., Seattle, Wash.
Delsasso, Leo P., Los Angeles, Cal.
Emery, Howard L., Worcester, Mass.
Evans, Willard M., Pittsburgh, Pa.
Evenson, Franklin F., Los Angeles, Cal.
Fleming, George A., Los Angeles, Cal.
Foreman, Walter E., Toronto, Ont.

Freeman, Newell L., St. Louis, Mo.
Fuller, Andrew B., Seattle, Wash.
Fung, Chien, Schenectady, N. Y.

Wear, Ralph H., Christchurch, N. Z.
White, Charles F. H., N. Woolwich, London, Eng.
Yamada, Yasutaro, Tokyo, Japan
Total 14.

STUDENTS ENROLLED OCTOBER 14, 1921

13549 Pilcher, Ernest G., New York Electrical School
13550 Schoenfeld, Kurt, New York Electrical School
13551 Mauney, Carl G., University of North Carolina
13552 Hyde, William W., Tri-State College
13553 Mylerly, James G., Bucknell University
13554 Decker, Blair L., Ohio Northern Univ.
13555 Hug, William S., Carnegie Inst. of Tech.
13556 Martin, Paul S., Worcester Poly. Inst.
13557 Wallisch, Cyril J., School of Engineering of Milwaukee
13558 Heineck, Albert H., Worcester Poly. Inst.
13559 Gourley, Thomas S., Spring Garden Inst.
13560 Clarkson, Charles N., Worcester Poly. Inst.
13561 Centeno, Jose G., Columbia University
13562 Davis, Dean H., University of Alabama
13563 Ritchie, R. Morris, Kansas State Agri. Coll.
13564 Lainhart, Vaughn R., New York Electrical School
13565 Hubbard, Frank A., Pennsylvania State College
13566 Hoffman, Raymond H., Pennsylvania State College
13567 Houser, Kenneth O., Kansas State Agricultural College
13568 Meyer, George A., Kansas State Agri. Coll.
13569 Barrington, Clarence R., Worcester Polytechnic Institute
13570 Maust, Charles I., Drexel Institute
13571 Needham, Charles H., Worcester Poly. Inst.
13572 Chen, Pao-cheng, Worcester Poly. Inst.
13573 Corby, D. K., Kansas State Agricultural College
13574 Wurst, Leroy L., Kansas State Agri. Coll.
13573 Kibler, Ray S., Kansas State Agri. Coll.
13576 Hopkins, Harold D., Kansas State Agr. Coll.
13577 Miller, J. M., Kansas State Agri. Coll.
13578 Brigham, Alden I., Worcester Poly. Inst.
13579 Smith, Lester D., Newark Technical Sch.
13580 Ladner, Henry Brooklyn Poly. Inst.
13581 Norwig, John, Jr., Brooklyn, Poly. Inst.
13582 Shaw, Bernard C., Worcester Poly. Inst.
13583 Tustison, Joe G., Kansas State Agr. Coll.
13584 Downing, Lloyd H., Kansas State Agr. Coll.
13585 Aydelotte, Oscar H., Kansas State Agricultural College
13586 Means, Lester H., Kansas State Agr. Coll.
13587 Hershey, Perry J., Kansas State Agri. Coll.
13588 Field, Russell M., Worcester Poly. Inst.
13589 Watts, Thomas R., University of Cincinnati
13590 Wass, Donald E., Purdue University
13591 McPherson, Charles G., Kansas State Agricultural College
13592 Nass, Vincent W., Kansas State Agr. Coll.
13593 Ebenstein, Charles S., Kansas State Agricultural College

OFFICERS OF A. I. E. E. 1921-1922

President
WILLIAM MCCLELLAN

Junior Past-Presidents
CALVERT TOWNLEY
A. W. BERRESFORD

Vice-Presidents
W. A. HALL
W. A. DEL MAR
J. C. PARKER
H. W. EALES
O. B. COLDWELL
N. W. STORER
C. G. ADSIT
F. W. SPRINGER
ROBERT SIBLEY
F. R. EWART

Managers
W. I. SLICHTER
G. FACCIOLI
F. D. NEWBURY
L. E. IMLAY
F. F. FOWLE
L. F. MOREHOUSE
HAROLD B. SMITH
JAMES F. LINCOLN
E. B. CRAFT
R. B. WILLIAMSON
A. G. PIERCE
HARLAN A. PRATT

Treasurer
GEORGE A. HAMILTON

Secretary
F. L. HUTCHINSON

A. I. E. E. COMMITTEES

(A list of the personnel of Institute committees will be found in the September issue of the JOURNAL, and will be published again in the December issue.)

GENERAL STANDING COMMITTEES AND CHAIRMEN

EXECUTIVE, William McClellan
FINANCE, L. F. Morehouse
MEETINGS AND PAPERS, E. E. F. Creighton
PUBLICATION, A. S. McAllister
COORDINATION OF INSTITUTE ACTIVITIES, W. I. Slichter
BOARD OF EXAMINERS, H. H. Norris
SECTIONS, A. W. Berresford
STUDENT BRANCHES, C. Francis Harding
MEMBERSHIP, E. H. Martindale
HEADQUARTERS, W. A. Del Mar
LAW, H. H. Barnes, Jr.
PUBLIC POLICY, H. W. Buck
CODE OF PRINCIPLES OF PROFESSIONAL CONDUCT, C. A. Adams
SAFETY CODES, H. B. Gear
STANDARDS, Harold Pender
EDISON MEDAL, C. A. Adams
RESEARCH, F. B. Jewett

TECHNICAL COMMITTEES AND CHAIRMEN

EDUCATIONAL, C. E. Magnusson
ELECTRICAL MACHINERY, B. A. Behrend
ELECTROCHEMISTRY AND ELECTROMETALLURGY, Lawrence Addicks.
ELECTROPHYSICS, F. W. Peek, Jr.
INDUSTRIAL AND DOMESTIC POWER, W. C. Yates
INSTRUMENTS AND MEASUREMENTS, P. V. Magalhaes
IRON AND STEEL INDUSTRY, E. S. Jefferies
LIGHTING AND ILLUMINATION, G. H. Stickney
MARINE, Arthur Parker
MINES, Graham Bright
POWER STATIONS,
PROTECTIVE DEVICES, H. R. Woodrow
TELEGRAPHY AND TELEPHONY, Donald McNicol
TRACTION AND TRANSPORTATION, H. M. Brinckerhoff
TRANSMISSION AND DISTRIBUTION, Edward B. Meyer

A. I. E. E. REPRESENTATION

(The Institute is represented on the following bodies; the names of the representatives may be found in the September issue of the JOURNAL and will be published again in the December issue.)

COUNCIL OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE
AMERICAN BUREAU OF WELDING
AMERICAN COMMITTEE ON ELECTROLYSIS
AMERICAN ENGINEERING COUNCIL OF THE FEDERATED AMERICAN ENGINEERING SOCIETIES
AMERICAN ENGINEERING STANDARDS COMMITTEE
BOARD OF TRUSTEES, UNITED ENGINEERING SOCIETY
ENGINEERING FOUNDATION BOARD
FRANCO-AMERICAN ENGINEERING COMMITTEE
JOHN FRITZ MEDAL BOARD OF AWARD
LIBRARY BOARD, UNITED ENGINEERING SOCIETY
ELECTRICAL COMMITTEE, NATIONAL FIRE PROTECTION ASSOCIATION
ENGINEERING DIVISION, NATIONAL RESEARCH COUNCIL
U. S. NATIONAL COMMITTEE OF THE INTERNATIONAL ILLUMINATION COMMISSION
U. S. NATIONAL COMMITTEE OF THE INTERNATIONAL ELECTROTECHNICAL COMMISSION
COMMISSION OF WASHINGTON AWARD

A. I. E. E. SECTIONS AND BRANCHES

A complete list of the 42 Sections of the Institute, with the names of the chairmen and secretaries, may be found in the September issue of the JOURNAL and will be published again in the December issue. A list of the 61 Branches will be published in the December issue.

ADDRESSES FOR 1922 YEAR BOOK.

TO THE MEMBERSHIP:

It will be appreciated if those members who are not certain that they have notified Institute headquarters of any change in business or mailing address made during the present year, will submit the information called for below at the earliest possible date.

F. L. HUTCHINSON,
Secretary

Vol. XL | DECEMBER, 1921 | Number 12

World Communication

BY ALFRED N. GOLDSMITH

Director, Research Department, Radio Corporation of America

IT is not intended, in this brief presentation of the broad outlines of the important subject of world communication, to do more than touch on the technical methods whereby communication is now being carried on or by which it is expected that communication will be carried on in the future. The subject matter is altogether too voluminous to permit more than a very general summary of the methods now in vogue or to be expected, and the setting forth of a general perspective of the problems involved and their relations. The writer must also indicate that his special interest in the field of radio communication has caused him to lay the main emphasis in this paper thereon, although, in a perfectly balanced paper on local and long-distance communication, the major portion would certainly deal with wire communication. While the writer has endeavored to minimize this lack of proportion in the paper, the reader is nevertheless advised to regard the paper as generally descriptive of the topics treated, but he should not judge the relative importance of the types of communication considered as proportionate to the space devoted to them.

Before proceeding further, the writer takes pleasure in acknowledging his indebtedness to Messrs. John L. Merrill and B. H. Reynolds of All America Cables, Incorporated, to Mr. A. H. Griswold, and Mr. O. B. Blackwell of the American Telephone and Telegraph Company, to Mr. Donald McNicol, to Messrs. C. H. Taylor, W. A. Graham, W. A. Winterbottom, P. Boucheron of the Radio Corporation of America, and to Mr. C. M. Yorke of the Western Union Telegraph Company, for the illustrations, information, and advice which they have so kindly furnished in connection with the preparation of this paper.

It must doubtless have occurred to every person who carries on business of importance, and indeed even to that ubiquitous individual, "the man on the street," that communication by direct transportation of the communicant is a most clumsy though necessary method. The carriage of the ponderous bulk of the human body from one point to another, merely to enable word-of-mouth communication, is doubtless an ineluctable necessity in many cases at present, and yet it is far from satisfactory. What is desired is the communication of intelligence, not the painfully long and tedious motion of the individual in whom the intelligence is embodied. To be sure, ordinary speech from man to man is a form of communication which, within a restricted range and for a given tongue, meets all ordinary requirements. But it becomes unsatisfactory as soon as we become removed from anyone to whom we wish to transmit our ideas. What we all desire is means so that we can get into immediate touch with all of those with whom we do business or with whom we take our pleasures. Our interest in communication then, is roughly dependent on the distribution of these people. Evidently we are the most interested then in transmission within a comparatively restricted area. In view, however, of the wide range of modern business and the widening range of personal travel, long-distance communication has also become of great interest to us.

It will be found that there are two well-defined methods of communication, each having its particular characteristics. Broadly, these may be termed "guided communication" and unguided communication." Ordinary speech, (unless it is particularly closely directed by a megaphone) is of the unguided variety. In other words, the energy radiated passes out freely in *all* directions enabling any one on the surface of a sphere, having the supposed aerially suspended speaker at its center, to hear, that is, to receive the messages equally well. As a general rule, methods of communication utilizing free wave transmission are entirely unguided, partly because of the difficulty of radiating a sharply defined stream or "searchlight beam" of radiation and partly because of the difficulty of preventing its subsequent diffusion or spreading in all directions through diffraction, refraction, reflection, and passage through diffusing media (for example, fog). As already hinted, the best rough approximation to a directed beam based on free wave propagation is the modern searchlight, which has indeed been used for military signaling and for light telegraphy and light telephony (photophone transmission). In no

Lecture delivered at the 372d Meeting of the A. I. E. E., New York, N. Y., November 17, 1921.

case of communication by free electromagnetic waves do we find anything like the definiteness of destinations and number of parallel channels which are achieved in wire communication, where we have remarkable results in the compression of a great number of separate telephone conversations within the same cable sheath.

Ordinary telephony and telegraphy, and "guided radio," "wired wireless," or "carrier current telephony and telegraphy," (as it is variously called) are all good examples of guided forms of communication. Here we have electromagnetic waves very closely guided in and by material conductors (wires) to a definite point of destination, and without sidewise radiation of the lengthwise propagated energy except where the distributed line constants suffer abrupt change.

Both guided and unguided electromagnetic communication depend on the transmission of electromagnetic waves through space. In unguided transs mission, which is generally known as radio, the wavespread out over a wide area and in this way may be picked up by a large number of receiving stations. In guided communication, generally known as wire transmission, the conducting wires form, as it were, electrical paths, which guide the waves to the exact point to which it is desired to send them.

Both of these methods have their advantages and disadvantages. In general they are not competitors of each other for overland working but supplement each other.

Modern radio communication is unguided, and hence can be received equally well at all points equidistant from the transmitting station. Here and there partially directed radio beams have been produced, principally for military purposes or for harbor radio beacons or the like. There are distinct possibilities of future developments along this line of directional radio transmission, naturally, by preference on the shorter wave lengths and over the shorter distances, though again within the limits imposed by the mechanism of wave radiation and propagation and in no case approximating even roughly to what can be accomplished by wire methods.

Guided communication differs from the unguided methods in that the signaling energy is directed along a well-defined path terminating, as a general rule, exclusively at the true recipient of the message. Of course, the true recipient of a *telegraph* message is the final receiving operator; the person to whom it is addressed receives only a letter transcript of the message, carried to him by a low-speed projectile method of communication, namely a messenger boy. But between the sending and the receiving operator on a metallic-return buried-cable telegraph circuit there exists what is to all intents and purposes a unique and completely definite path. In strictest accuracy this statement would have to be modified because of the leakage of current from telegraph conductors, the induction of currents in nearby conductors even from circuits made up of twisted pairs of conductors, and the radiation of electromagnetic waves from a telegraph circuit during the transient conditions. Most of these effects are, in general, inappreciable and may be neglected for the moment, although their effects in long telephone circuits require careful consideration.

It appears that both guided and unguided communications have noteworthy characteristics and real spheres of usefulness. The advantages of guided communication are the much greater ease of securing secrecy of communication and freedom from "tapping," the higher efficiency of energy transmission, the definite and known nature of the destination of the message, and the comparative ease of establishment of a compact many-channeled communication network.

It is interesting to note that the *efficiency of energy transmission* by unguided systems of communication is practically nil. The approximate ratio of radiated power to receive power for fair transoceanic communication via radio is of the order of one hundred trillions to one. And by no means all of the power available in the antenna or radiating system of the transmitter is actually radiated. The efficiency of the mere act of radiation may be from roughly 50 per cent down to a per cent or two. The efficiency of transmission of energy over even a long telephone circuit or submarine cable is incomparably greater than the value given for unguided communication having a highly disadvantageous law of attenuation or diminution of signal amplitude with distance. Nevertheless, the *efficiency of communication* may be very high for unguided signaling, both as a system for transmitting intelligence and as an economical means for such transmission. Thus, the cost of accurately sending a message across the ocean via radio compares very favorably with the cost of transmission by submarine cable. That is, there is an approximate balance between the high cost of the long submarine cable and its comparatively inexpensive terminal stations and the high cost of the radio transmitting station, the low cost of the radio receiving station, and the zero cost of the medium of transmission. The balance is such as to indicate that the question of the intrinsic efficiency of energy transmission does not properly enter into a consideration of the real value of a communication system. It must not be inferred that the efficiency of energy transmission is without importance in comparing different types or systems of unguided communication with each other but only that it is not a suitable criterion for judging the commercial usefulness of an unguided system of communication as compared with a guided system.

It appears that unguided communications, such as radio, are preeminently fitted for broadcast service and will find a wide application in this direction. At

present both the United States and Germany are using radio for the dissemination of information, and practically all the larger countries use it for broadcasting time signals, hydrographic information and the like.

The principal problems connected with radio communication, selected as a typical and effective form of unguided communication, are those connected with the avoidance of atmospheric disturbances of reception and those connected with the mutual interference of various transmitting stations.

It appears that there originate in the atmosphere, in a fashion not entirely understood, a number of forms of electric disturbances which tend to interfere with radio signals. Under favorable conditions, and with the most modern forms of receiver for eliminating such disturbances, their presence would hardly be suspected; on the other hand, in the middle of a lightning storm in the vicinity and with unsuitable receivers, all communication will be interrupted. As a result of determined research, there have been produced forms of receivers which markedly reduce the effect of such electric strays, and enable good communication to be fairly continuously maintained. It is to be expected that the normal further evolution of radio receivers, the increase in transmitter power, and the skilful handling of traffic will lead to *continuous* commerical communication regardless of these undesired intruders.

The use of the ether as a common channel for all radio messages is not an unmixed blessing. At times it leads to situations paralleling those encountered by the urban dweller who has many musically inclined neighbors, all of whom simultaneously persist in utilizing the available air for powerful acoustic radiation. The gratification of the listener is markedly diminished under such conditions of "interference" or "jamming" as it is termed by the radio operator. Monofrequent radiation and audio-frequency selectivity suggest themselves as the first type of solution in the acoustic case mentioned. For radio communication, we have aimed at as nearly monofrequent or "monochromatic" radiation as possible from the transmitting station, and the use of radio-frequency selection at the receiving station. This method is, on the whole, very effective and enables a considerable number of mutually non-interfering radio channels to be in simultaneous operation. In addition to frequency selection, in its several most recent forms, we have available directional selection. This latter involves the use of special antenna systems at the receiving station which respond most powerfully to signals coming from one or more directions. While the development of directional reception is still in its earlier stages, it is possible to reduce interference considerably by this means. Directional reception has other practically useful applications in the guiding of ships in times of fog or storm, using either the "radio compass" or the "radio beacon." In the former case, the directional receiver is located on land, and the ship is located during its transmission by triangulation between two or more land stations. In the latter case, the directional receiver is on the ship and its location is determined by triangulation on board ship after finding the bearing of two or more known land "beacon" stations which send out their indentification signals more or less steadily.

The establishment of the radio analog of "order wire circuits" is entirely possible, and leads to no particular difficulties. On the other hand, the development of effective radio ringing methods, which enable dispensing with the constant attendance of an operator, for example on board ship, is still in its earlier stages. This is not a serious drawback at present since the transoceanic circuits run nearly continuously and therefore require the constant attendance of operators in any case, and in the marine service it is very desirable to have an operator on duty at all times to pick up faint distress calls and hydrographic information (storm warnings and the like). However, the development of effective and reliable call signal systems may become of more importance for unguided communications as time goes on.

While two-way communication is readily possible through direct speech, that is, by the use of unguided air waves, true duplex communication is not so easily obtained. The essential element in full duplex communication is that there shall be two streams of signals flowing in opposite directions simultaneously and without mutual interference. Thus there are required two transmitters and two receivers, which influence each other only in pairs. In radio communication, full duplex communication is readily obtained and is, in fact, used largely in the transoceanic service. In the marine services, on the other hand, the users are generally content with two-way communication wherein the two parties to the communication take turns at sending and receiving alternately. The traffic-carrying capacity of a circuit is more than doubled by the substitution of full duplex for two-way service since the correction of errors is then more readily effected without delay and the coordination of traffic on both sides more easily carried out. It is interesting to note that not only duplex but even multiplex radio communication is possible on a single frequency or wave length by the use of audio or superaudio frequency modulation. That is, continuous waves of a certain length are modulated or controlled at a frequency lower than the wave frequency and the reception is accomplished with double selectivity; namely, an initial selectivity to the actual wave frequency followed by a selectivity toward the lower or modulation frequency. By thus building a lock which requires the simultaneous use of two keys to open it, we can increase the selectivity of receiving stations. It is not believed, however, that the ultimate total traffic-carrying capacity of the ether is increased in

this way, even though it avoids admirably certain present-day difficulties and has a real sphere of usefulness.

If we revert to the broadest aspects of the problems of world communication, we find that an ideal system can be imagined which would presumably meet all reasonable requirements. This would be a continuously operative interference-free person-to-person network. It should include every person on the globe and clearly carry speech, which, it is hoped, would be in some lingua franca or universal language. Thus baldly stated, the problem seems frankly insoluble in terms of agencies now available. Yet it is not difficult to imagine equivalent systems which would constitute something better than a first approximation to this remarkable plan. Let us imagine a very large number of telephone substations located at all convenient points. Most of these substations will be fixed, and connected by wire line to the central stations or exchanges. However, there may be in addition movable substations which will, of course, be generally connected by radio

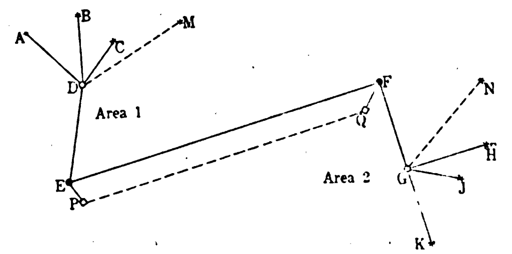

FIG. 1—SCHEMATIC COMMUNICATION NETWORK EMBRACING WIRE AND RADIO SYSTEMS

to the central offices. As examples of such movable substations we may take ships, railroad trains, and aircraft equipped with radio telephone sets, or in special cases individuals supplied with highly portable radio telephone outfits. We may expect that even individuals, such as forest rangers and other groups of professional patrolmen, would make good use of such portable substation equipment. The central offices will be connected with each other, directly or indirectly, by wire systems where wires can be more effectively and economically maintained, and by radio where wires cannot be maintained. In Fig. 1 is shown schematically the layout of such a system including, however, only two of the communication areas.

We will suppose that person A in area 1 desires to speak to person H in area 2. Substation A is connected by wire to central office D of area 1. Thence the speech currents travel to the "long-distance" exchange at E. From E the speech travels by wire or radio to F, the "long-distance" exchange nearest to G, the central office of area 2. If the radio route is used, the radio stations P and Q, controlled by E and F respectively are employed. After passing to G, the speech is sent directly to H, the called station. At various points along their path, the speech currents are amplified as necessary. In case a movable substation desires to share the facilities of such a communication system, it will do so by establishing radio telephone communication with a radio station at the local central office or a radio station directly connected thereto. Thus if an occupant of the railroad train M provided with a radio telephone set, desires to use the telephone system shown, he does so by establishing communication with D by radio. A movable substation at N could similarly share the benefits of the system by connecting with central office G by radio. So that we can even imagine direct communication between stations M and N, both in motion, through this communication plan. It will be seen that communication with moving substations, and telephone communication across oceans, will probably be on a radio basis in this system, and that all the remaining portions of the communication (which constitute the major portion of the communication network in practically all cases) will be by wire. The particular system described illustrates the judicious and useful combination of guided and unguided systems of communication, though it represents an extreme case and a very small percentage of the total telephone traffic handled.

The great bulk of communication is now carried on by wire methods. There is no question but that wire transmission must always carry the great bulk of communications, particularly in the well settled and highly developed parts of the world where its methods permit the setting up of reliable and economical paths for carrying tremendous numbers of messages without mutual interference.

Radio, however, has an important field to fill, as an auxiliary of the wire system in extending service to ships at sea, to aeroplanes, perhaps even to automobiles, and in general to moving bodies to which wires cannot be connected. It has a pioneering field in undeveloped countries, or wherever natural barriers make it difficult to set up the wire system. It has perhaps its most profitable and commercially useful field in giving service between continents separated by wide reaches of ocean.

The possibilities of guided transmission can be well illustrated by two examples: First, the transcontinental line between New York and San Francisco, which is today giving high-grade commercial service between the cities of our eastern and western coasts. The second is the 1200 pair subscribers' cables, now being placed by the telephone companies, which permit of 1200 simultaneous conversations being transmitted through a sheath of less than 2.5 inches, inside diameter.

Two other illustrations which will likewise indicate the possibilities of radio are: First, the radio telegraph service from the eastern coast of this country to all of the countries in Europe. Second, the radio broadcasting stations, which have been set up and which permit all of those within range of these broadcasting

stations who have the necessary apparatus to pick up the news and entertainment which is sent out from the stations.

For the case of long-distance wire communication in certain of the more important countries, such systems as those required in the previous plan already exist to a considerable extent. For the corresponding inter-

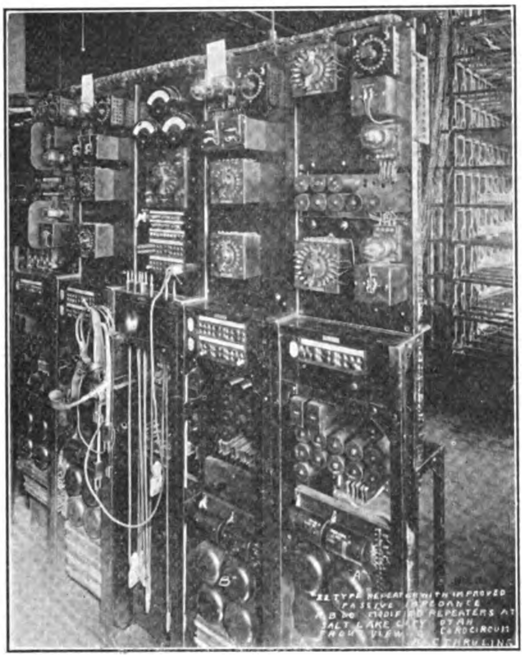

Fig. 2—Long-Distance Line Telephone Repeater Installation A. T. & T. Co., Salt Lake City, Utah

national transoceanic network, involving radio telephone trunk circuits, the surface has not yet been scratched, although the recent remarkable demonstrations by the American Telephone and Telegraph Company of telephone service from Catalina Island to Havana indicate the extent to which this problem is engaging the attention of investigators and firing the imagination of far-seeing executives of communication companies. In the case mentioned, telephone communication was established between two points thousand of miles apart, separated by portions of two oceans, and across a continent. The speech was sent from Catalina Island across a stretch of the Pacific Ocean via radio, thence by wire line across the United States and down to Key West, Florida, and finally through the submarine telephone cable to Havana. The transmission difficulties were equal to those in bridging the stretch from London to Pekin, or from New York to Buenos Aires, as pointed out by Dr. J. J. Carty. It is likely that for a long time mankind will find that a very approximate approach to the system of world communication previously described will satisfy the most ambitious engineers and traffic experts. The omission of the portable substations *M* and *N* would work no great hardship at this time, particularly if the number of conveniently located substations such as *A*, *B*, *C*, and so on is continually increased into a practically all-embracing system.

The subscribers' local telephone stations (such as *B* and *J* of Fig. 1) already exist to a considerable extent in some parts of the world. Thus in the United States, there are 12,600,000 stations of this type in existence, interconnected by 25,400,000 miles of wire, and carrying more than eleven billion messages annually. This is one telephone per nine persons of the population, roughly, and approximately four telephones per square mile for the entire area of the country including its uninhabitable portions. Obviously we are approaching an era of truly universal communication service, when a modern country can show a telephone network such as that of the Bell Telephone System connecting over 70,000 cities, towns and rural communities. Some of the component elements of such a vast communication system deserve attention. Starting from long-distance exchanges, such as that in New York, the lines radiate in all directions. Careful "loading" of the lines prevents distortion of the speech. At intervals the attentuated line currents are automatically amplified in "repeater stations," such as that at Salt Lake City shown in Fig. 2. These land line circuits may be automatically extended through submarine telephone cables. Or radio telephone transmitters

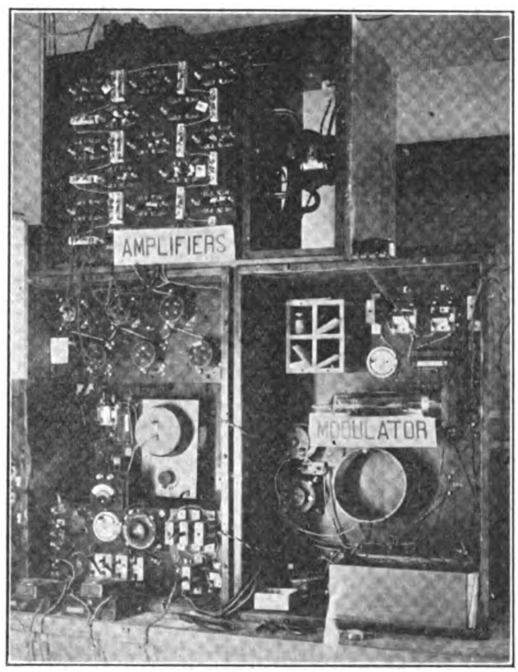

Fig. 3—Amplifier and Modulator Equipment of Radio Telephone Station, Arlington, Va.

may be used as extensions of the land line system. Thus Catalina Island is connected to the California mainland and the Bell telephone system through a radio telephone link. Not only is perfect duplex telephone service maintained over this combined wire and radio circuit, but the introduction of the radio portion of the circuit does not change even the details of handling

traffic. For instance, the circuit is so arranged that it is possible to "ring through" the radio portion for calling purposes as well as to talk over it! The amplifying and modulating equipment of a radio telephone transmitter at Arlington, Virginia, which carried speech transferred from the wire lines of the American Telephone and Telegraph Company to Hawaii and Paris, is shown in Fig. 3.

It is obvious that in the future, wire communication will be supplemented by radio communication; the wire system being used for local distribution and for long distances, save where large bodies of water, the mobile nature of the receiving station, natural barriers, or other special conditions obtain; and the radio system for the cases just mentioned and for broadcasting services.

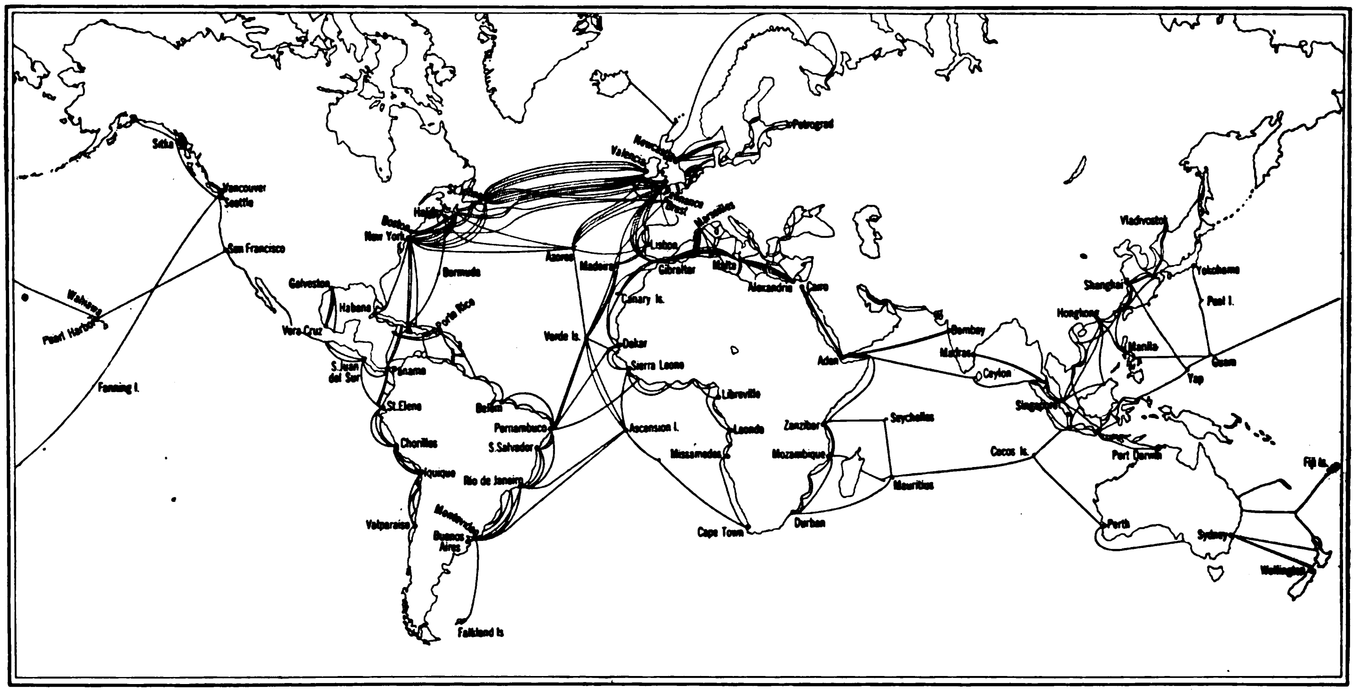

Fig. 4—Map of Present Submarine Telegraph Network of the World

The development of wire communication both in magnitude and quality has been one of the most remarkable achievements of pure science and technology in history, and this development is proceeding surely and rapidly to more useful stages. We need only consider briefly a few of the lines of modern endeavor in the field of wire communication to appreciate something of what the future has in store. By the use of modern multiconductor cables, storm-proof lines have become widely available and enable an immense number of messages to be carried simultaneously within the same cable sheath without mutual interference from each other. By methods of mutual interconnection (such as the so-called "phantom" circuits) each conductor may carry more than one message without interference. The use of carrier currents permits the further and wider utilization of conductors for a still greater number of independent channels. By "loading" the long lines suitably and providing them with vacuum-tube amplifiers or repeaters, the range of commercial transmission has been increased to a hitherto unbelievable extent. And the duties of the skilled operator are being handled more and more by highly ingenious automatic equipment. In telephony, machine switching is expected to replace largely the central operator, and in land line telegraphy, printing telegraph equipment is reducing the volume of manually transmitted and aurally received traffic.

The integration of wire and radio systems, at least from the operating standpoint, is one of the promising possibilities of the future. As has been indicated above, these systems are mutually supplementary and can best serve the public when each fulfills those duties for which it is most suited. So far as economic and service possibilites are concerned, the guided systems of wire communication promise the more important future developments in the field of normal overland communication, although there is no doubt that a valuable service of increasing magnitude will be furnished by radio communication. In the field of overseas communication, it is believed that for some time there will be a very helpful coordination of cable and radio communication to the advantage of each and with a resultant improved service to the public. There is probably no field where cooperation between the various agencies is more important than in the field of universal communication.

The cable network of the world, shown in Fig. 4, indicates that much has been achieved and that not

a little remains to be done before high-speed direct service from each country to every other shall be available. It will be noted that Europe and North America are the radiating centers of cable communication, and that the North Atlantic boasts the greatest number of transoceanic cables. There are, indeed, no less than seventeen such cables across the North Atlantic. On the other hand, South America, Africa, and Australia have a smaller number of cables and more indirect service. In the case of South America, this situation is being vigorously and markedly improved. While many of the cables have clearly been laid for commercial use and financial profit, others have apparently been laid for military or strategic reasons. A close study of the map and cable statistics will indicate the preeminence of England in this field of communication. This is partly a natural response to the needs of the far-flung British Empire, partly

FIG. 5—TRANSATLANTIC CABLE STATION BUILDING AT PENZANCE, ENGLAND

the result of early experience in the cable operating art, partly in consequence of the possession of an unusually ample supply of high-grade gutta-percha such as is used for cable insulation, and partly the just reward for foresight and planning of adequate communications. It is to be noted that the United States is rapidly forging ahead in the cable field, particularly in the improvement of communications of the Western hemisphere.

Some idea of the scope and methods of an extensive cable system can be gained from Figs. 5 and 6, which illustrate stations and apparatus of the Western Union Telegraph Company. It is in such distant outposts of civilization that the communication of the populous centers of the world is maintained. At such points, after a journey of thousands of miles beneath the ocean, the message finally actuates the delicate apparatus necessary for its recording and decipherment. The dignified and sturdy appearance of the buildings which house this apparatus is indicated by Fig. 5, showing the cable station at Penzance, England. Besides the actual transmitting and receiving apparatus, much auxiliary equipment properly finds its place

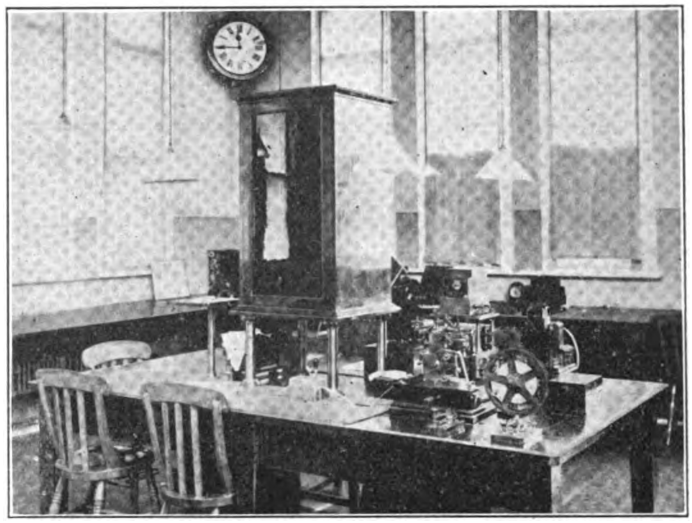

FIG. 6—MODERN TYPE OF SIPHON RECORDER USED IN CABLE TELEGRAPHY

in the modern cable station. An actual siphon recorder at Penzance, seen at close range in Fig. 6, illustrates the form of apparatus which draws, on the moving paper tape, the waving line from which the skilled operators translate the cable messages of the present day world.

As a further illustration of the latest methods of handling cable traffic, there is shown in Fig. 7 some equipment of the All America Cables, Incorporated. While the message is being sent, it is carefully checked

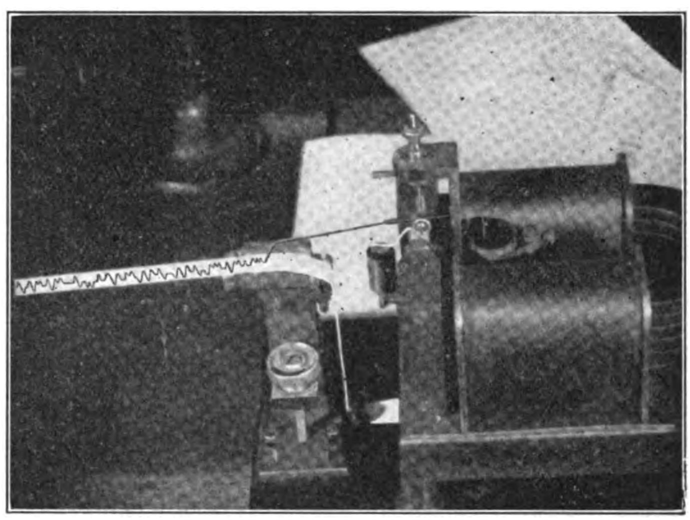

FIG. 7—"BABY" SIPHON RECORDER USED BY CENTRAL & SOUTH AMERICA TELEGRAPH COMPANY

by typewriting it from a tape record made by the "baby recorder" of Fig. 7. At the receiving station, the messages are recorded by the siphon recorder,

the waving line on the tape then passing before the receiving operators who again typewrite the message. When high-speed reception is practised, it becomes necessary to have several operators transcribing the tape from each recorder, and this is done by an ingenious system whereby each of the successive operators passes his "overflow" message to the next further operator.

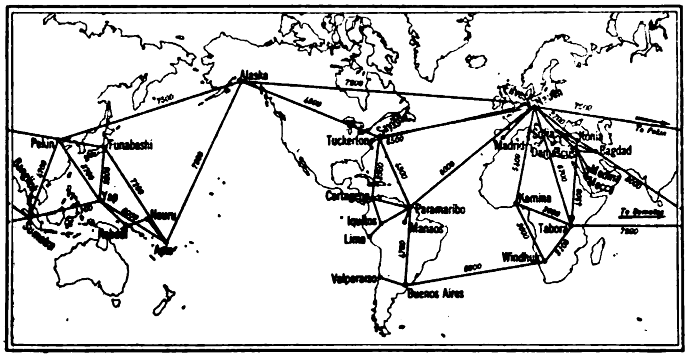

Fig. 8—German Scheme of 1913 for World Communication

Complicated as are the mechanical and electrical details of the apparatus used and prosaic as may be the daily routine of those who manipulate the apparatus, the dullest imagination cannot fail to perceive the underlying romance and inspiration of this quiet but powerful conquest of space, and none will fail to admire and praise the fortitude and vision of the early pioneers who made cable communication possible, and of their successors who have brought it to its present capabilities.

A number of world schemes of radio communication has also been proposed in the past, and some of them are in the process of present realization. The earliest one is shown in Fig. 8. (Here the distances are given in kilometers.) It represents the extremely ambitious

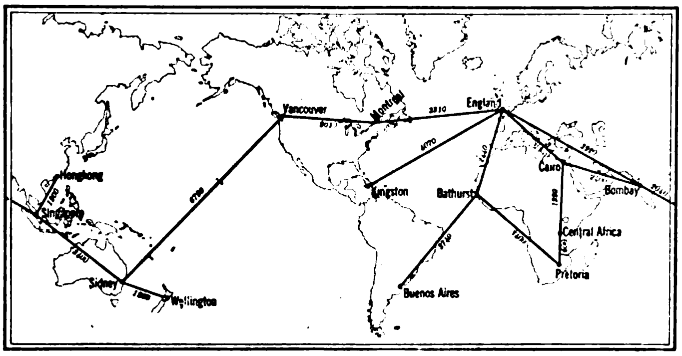

Fig. 9—British Imperial Communication Scheme of 1913

German scheme of 1913 and is clearly influenced to a great extent by military as well as commercial considerations. The length of some of the jumps from station to station, taking into consideration the transmitter powers and the types of receiving apparatus, then available, indicate that only partial or occasional service could have been expected over the longer spans, and then only at low speeds. It also appears that each station was to handle several channels and therefore presumably to divide its time between its various correspondent stations. This type of service is more suited to press and propaganda work and light traffic than it is to the more exacting high-speed commercial requirements. This plan was not carried far before the war brought about its complete destruction.

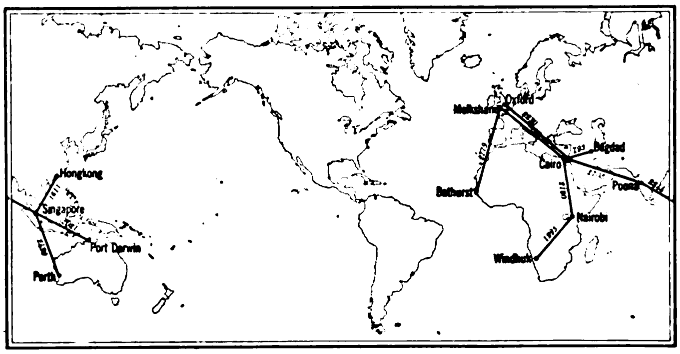

Fig. 10—British Imperial Scheme of 1919 for Radio Communication

Fig. 9 (on which the distances are in nautical miles) represents the first of the British Imperial schemes for radio communication, the so-called "All-Red Chain." It dates from 1913, and was the plan of the British Marconi Company which submitted it to the British Government for approval. It was adopted, and some work was done along the lines indicated when the war intervened. The changes caused by the war and other causes led to its discontinuance and to rather serious differences between the British Government and the Marconi Company. Afterwards the claims of the Marconi Company were in part allowed and suitable financial compensation paid by the British Government for the loss of the original contractual

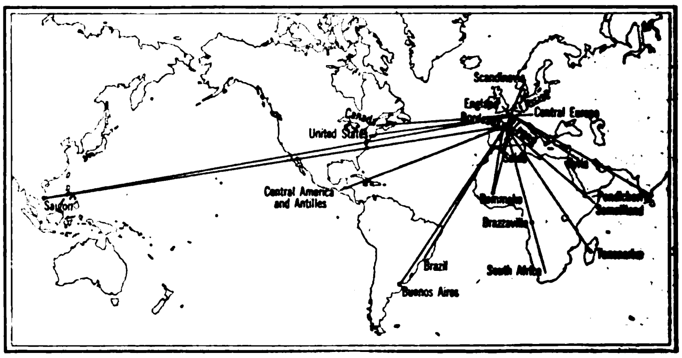

Fig. 11—French Communication Scheme

profits. The plan itself included two routes from England to Australia with only two relays. It was a scheme involving long spans. London was the main center from which most of the communication to distant points radiated directly.

In 1919 and 1920, a British Government Committee reconsidered the entire project of the Imperial

radio scheme, and recommended the less ambitious plan given in Fig. 10. Here the Western Hemisphere is apparently neglected, London is not connected directly (without relays) to the more distant points, the average span is shorter, and the terminal points chosen are dictated apparently only in part by commerical considerations. This system will be Government-owned and operated, which may account for the nature of this plan, which is now being carried out. Only a very small portion of this plan has been carried out so far.

Another very ambitious plan is due to France and is given in Fig. 11. It, too, is not planned entirely along commercial lines. Furthermore, it is clear that the French stations are intended to divide their time between a number of terminal stations and that extemely long spans are planned. Of the stations shown on the French plan, several are built and several more are in the process of construction. A considerable portion of this plan will, however, still have to be worked out in the future. It is noticeable that both the present French plan and the original German plan lay more stress on South American traffic than does the present British Imperial scheme.

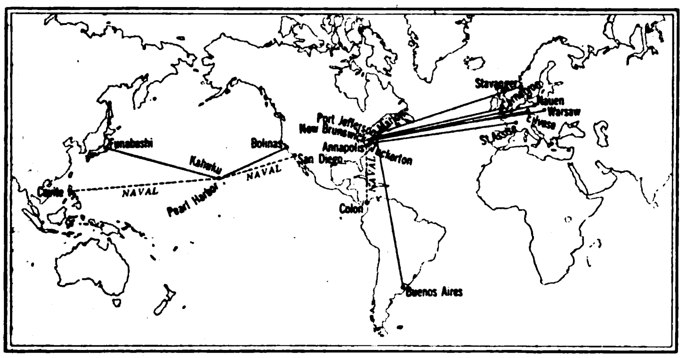

FIG. 12—COMMUNICATION SCHEME OF AMERICAN ORIGIN

The communication system shown in Fig. 12 is that of the United States and differs in several important respects from the preceding plans. In the first place, *every station* shown thereon is either in operation or under construction, and by far the greater portion of the stations are those already in operation. Furthermore, for the sake of clearness, the large contemplated expansions of this plan are not shown on the diagram although they will add nearly as many more channels of communication to the system as those already shown. In the second place, the plan shown is preeminently a commercial one, both in the placing of the terminal stations and in the practically exclusive use of each American station for a single channel. This latter feature permits the speedy handling of large volumes of traffic and avoids the troublesome delays which result when the time of a transmitting station is excessively "chopped up" or divided between too many receiving stations. The system is one of moderate and long spans, this being dictated to some extent by the geographical location of the United States, its particular communication needs, and the absence of American possessions at certain points. The needs of the United States, considering these circumstances, have very greatly stimulated the technical improvement of radio communication, and have led to the satisfactory solutions of the problems of long-distance radio communication. The case is an interesting illustration of the stimulating and helpful influence of natural obstacles.

It is hardly profitable, as matters now stand, to consider television and telestereotypy in connection with world communication. By television we mean the transference of an image or picture from one point to another other than by the use of light waves or the physical transportation of a material object. There are two general classes of television, the instantaneous and the deferred. In the case of the instantaneous type, the picture visible at the receiving end of the channel corresponds with that at the sending end practically at that moment. In general, such systems would be capable of producing moving pictures at the receiving end. There have been some partial approaches to this system for monochromatic pictures of simple objects such as could be readily synthesized from a comparatively small number of square picture elements of controllable luminosity. However, it is not worth speculating yet as to the practical value of such a system. In the deferred system, the picture is divided into dot or linear elements which are sequentially transmitted over the circuit with what is practically a simultaneous indication of their luminosity and with an appropriate means of synchronizing the receiving transcriber element motion to that of the transmitter element motion. In most of those systems, light-sensitive substances such as selenium form the basis of the process. Pictures can also be transmitted by dividing the entire picture into reasonably small elements and sending a code message systematically covering the brightness of each picture element. This is naturally a tedious procedure, and we are told that three hours were required for the transmission of a moderately complicated picture across the Atlantic by this method which, however, requires no special transmitting or receiving apparatus. Neglecting for the moment the broadcasting of the personal appearance of errant criminals, and certain military applications, there seems to be no great demand for television and it is not to be expected that its progress will be rapid. This is even more the case for telestereotypy or the reproduction of solid objects in their three dimensions at the receiving end. In fact, telestereotypy at present is purely an interesting problem for which a number of general plans of investigation have been suggested.

On the other hand, printing telegraphy is of more general interest. In the various printing (or writing) telegraph processes, special signals, other than the

usual Morse code signs, are sent over the wire or radio circuit, and, at the receiving stations, control the func-

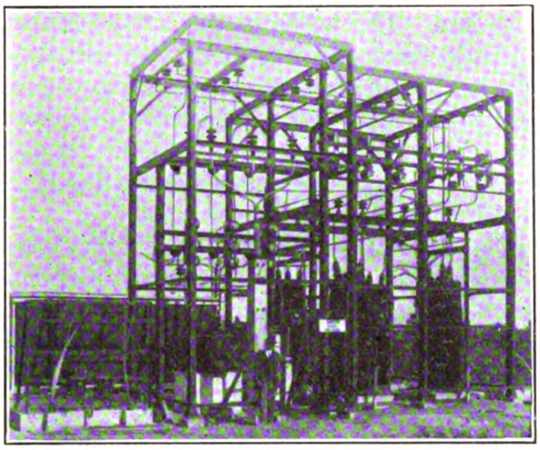

Fig. 13—Outdoor Substation at Radio Central, Long Island, N. Y.

tioning of an electrically operated typewriter or equivalent writing machine. In some cases, the material is printed on a continuous tape whereas in other cases the received signals are printed line by line on message blanks. In the latter form of so-called "page-printers," there are "line spacing" and "carriage return" signals which are sent at the correct times from the transmitter and which accomplish the corresponding results at the receiver. The transmission in the case of printing telegraph systems, and indeed of all high-speed systems, is from narrow paper tape which is perforated by hand or on a perforating typewriter and then run through a Wheatstone high-speed transmitter or a similar automatic transmitter. Provided care is taken in the perforation of the tape, the sending by this means is more uniform and reliable than with hand sending.

It has long been known that traffic from one country to another is by no means evenly distributed throughe out the twenty-four hours of the day, the days of the week, or the months of the year. There are very pro-

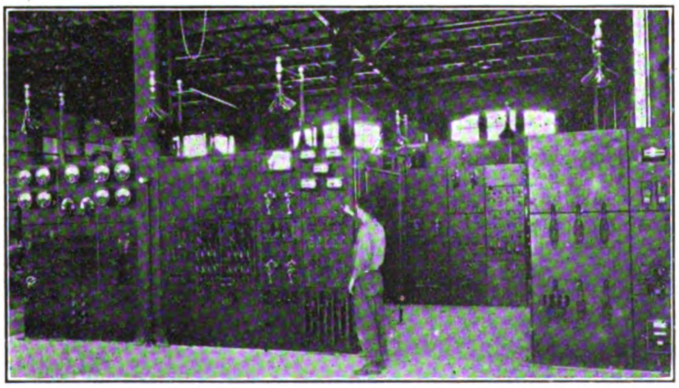

Fig. 14—Sections of Control Switchboards, Radio Central, Long Island, N. Y.

nounced peaks, and depressions or lulls of traffic found to exist. Thus, the traffic between two countries will generally be heaviest for the hours during which daylight is common to both, and will drop to a minimum during the week end. It would be desirable to handle the peak of the load without permitting traffic to pile up, but this may not always be feasible for reasons of

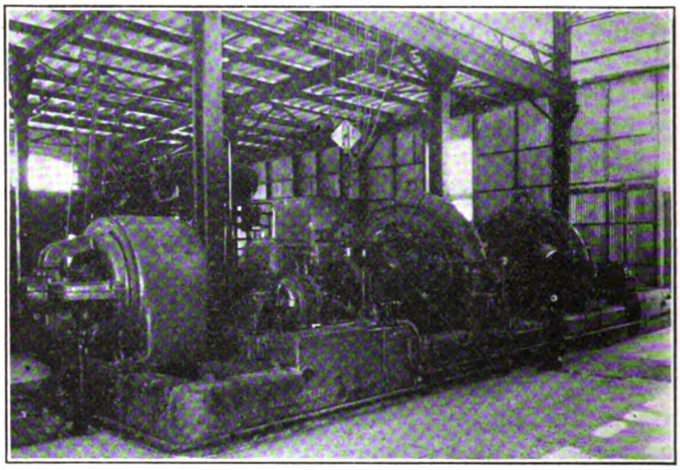

Fig. 15—Alexanderson Alternators Installed at Radio Central, Long Island, N. Y.

economy, both of equipment and of necessary personnel. This has led to the attempt to secure a high load factor for communication circuits by encouraging some of the users of the service to accept a certain delay in the delivery of their messages which are then sent at a reduced rate. Thus we find in addition to normal messages, which are sent in the order in which they are

Fig. 16—Land Line Telegraph Equipment Connected to Control Operation of High-Power Radio Transmitter

received the "deferred" messages which are sent at the earliest opportunity when traffic has slackened sufficiently to permit their introduction. "Night letters" and "week end letters" are sent during the periods indicated, and are obviously intended to fill an otherwise dull period in the circuit. On some circuits, "urgent" messages are accepted which take priority over all others, and require the payment of a considerably increased rate. As a general rule,

the minimum number of classes of messages required to maintain an acceptable load factor is desirable, not only because of the increased routine in handling traffic of many different classes but also because of the confusion in the public mind and the possible dissatisfaction which results when the type of service rendered in any given case is not clearly understood in advance.

A fairly definite idea of what is required for the transmission and reception of messages on a modern radio circuit can be gained from the following series of illustrations covering stations and equipment of the Radio Corporation of America. The power required to operate the great transmitters enters the station from an outdoor substation, such as that at the New York Radio Central on Long Island, shown in Fig. 13.

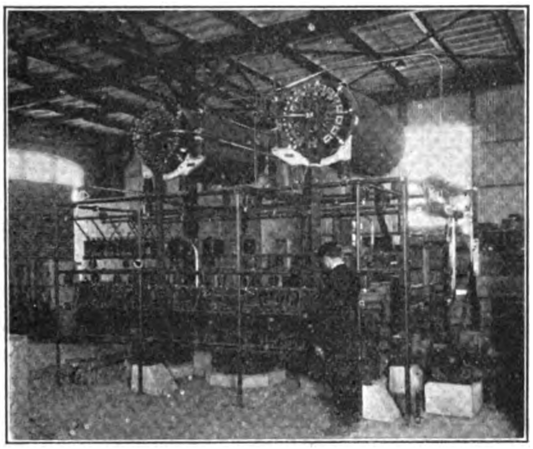

FIG. 17—MAGNETIC AMPLIFIER EQUIPMENT AT RADIO CENTRAL

Complicated switchboards, such as that shown in Fig. 14, enable the control of the many hundreds or even thousands of kilowatts required for the station. We then reach the heart of the transmitting station, namely, the radio-frequency generators which produce hundreds of kilowatts of very high-frequency energy. The two Alexanderson massive alternators already installed at the Radio Central are shown in Fig. 15. The machines represent years of research and development and are among the most remarkable products of modern engineering. The frequency of the currents produced by those in the illustration is no less than 20,000 cycles per second! To pass for a moment to the opposite type of equipment, there is shown in Fig. 16 some of the conventional telegraph equipment which controls a transmitting station when working at hand speed. When working at high speed, automatic transmitters controlled by perforated paper tape are employed.

It has always been a problem to control several hundred kilowatts of power at frequencies of 20,000 cycles per second by breaking it up into the dots and dashes of the Morse code at speeds as high as 100 words per minute or more. When it is considered that this is equivalent to starting and stopping the flow of power fifty times per second, accurately and faultlessly, and that the initial control power is merely the few watts that can be drawn from the terminals of a telegraph line, the magnitude of the problem becomes evident. By the development of high-speed power relays and the new "magnetic amplifier," the

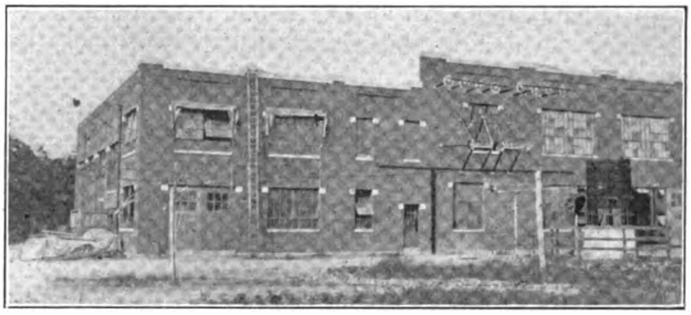

FIG. 18—RADIO TRANSMITTING STATION AT MARION, MASS

problem has been very elegantly solved. The magnetic amplifiers at Port Jefferson are shown in Fig. 17. These ferromagnetic devices accurately modulate or control the flow of power from the alternators to the radiating system or aerial wires. The antenna or aerial wire currents then pass out from the station building through wires supported on special radio frequency insulators. The arrangements employed are given in Fig. 13, which also shows that the modern radio transmitting station (as at Marion) looks much more like a conventional moderate-size power plant than the radio stations of ten years ago, which rather resembled a small physical laboratory.

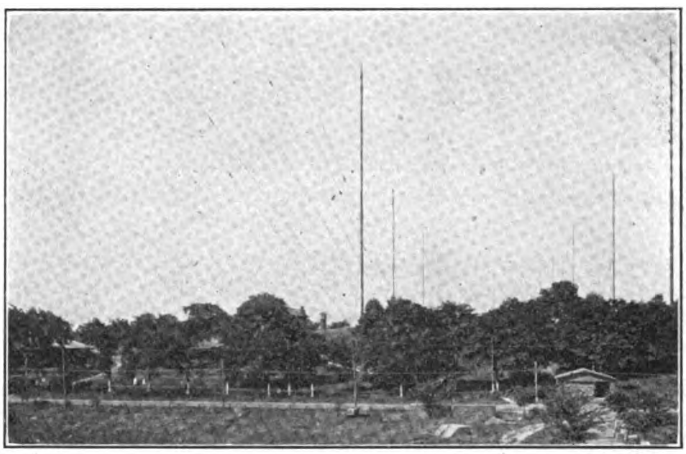

FIG. 19—RADIO ANTENNA STRUCTURE AT NEW BRUNSWICK N. J.

To radiate the large amounts of power required to bridge transoceanic stretches, a large and lofty radiating system or antenna is required. The main tower at Tuckerton is 850 feet (250 meters) high. A type of antenna system is pictured in Fig. 19, this being the structure at New Brunswick. A row of 400-foot masts stretching 6000 feet from the station support the "multiple tuned" antenna system. The latest

form of antenna support is shown in Fig. 20. It consists of a line of 400-foot towers with 150-foot spreaders at the top of each, and stretching a mile and a half from the station. Twelve such rows of towers, each fed by its own alternators and constituting in effect a separate transmitting station, are to be erected at the New York Radio Central located near Port Jefferson, Long Island. An area of about ten square miles is being devoted to this giant station, which will be by far the largest in the world when completed.

In radio reception there have also been very marked advances during the last few years. Each row of apparatus in its specially shielded cases is capable of handling one transoceanic channel. Each operator is provided with a telegraph key controlling the transmitter on the corresponding circuit, so that he can, if necessary, "break" or interrupt the transmitting operator to obtain a correction or other information

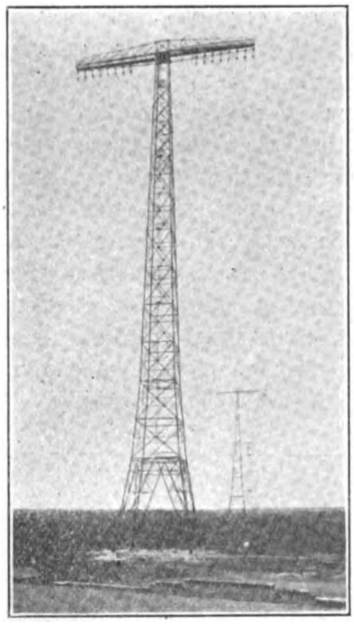

FIG. 20—ANTENNA TOWERS AT RADIO CENTRAL, LONG ISLAND, N Y

from the station which he is receiving. When reception at high speed was desired, recording was sometimes accomplished on modified phonographs which were run rapidly and the records were later transcribed at lower speeds by a number of operators. This method of receiving at high speed has been superseded by modern forms of ink recorders specially developed for radio reception. Such an ink recorder is shown in Fig. 21, and the details of its construction and use will be described in papers shortly to be presented before an engineering Institute. The Broad Street, New York, operating room with some of its recorders installed is illustrated in Fig. 22.

At the New York Radio Central on Long Island, the seventy-two towers previously mentioned cover an area which stretches nearly halfway across Long Island. It is perhaps unfortunate that the eye of man is not capable of perceiving the long wave light which will be radiated from this station, or, as it is more commonly called, the radio wave. If this light were but visible, the pulsations of the dots and dashes sent from the twelve radiating aerial systems would appear to the distant observer as brilliant flashes emanating from a tremendous blazing hemisphere surrounding the station area.

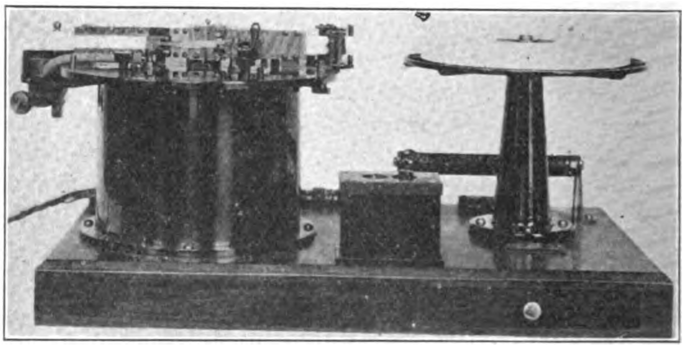

FIG. 21—INK RECORDER USED TO RECEIVE RADIO SIGNALS

As has been mentioned, wire and radio communication should work hand in hand in any comprehensive scheme of world communication. The land lines and cables have very clearly demonstrated their great capabilities and usefulness, but radio communication, even at this early state in its development, has shown that it should be considered as an integral element of any well-considered plan for communicating all over the globe. Today approximately 15 per cent of the traffic across the Atlantic from the United States is handled via radio, which is a hopeful showing for a

FIG. 22—NEW YORK CITY OFFICE OF RADIO CORPORATION OF AMERICA

new art. To the extent that there is harmonious and intelligent cooperation between the various communication systems, we may hope for the satisfactory solution of the problem of giving every person on earth rapid and reliable communication. Fortunately there are no physical limitations to prevent the interconnection by skilled persons of wire line and radio circuits.

Messages received by radio telegraphy or radio telephony can be automatically transferred to wire lines and over them relayed to any point reached by them. Conversely, telegraph or telephone signals on a wire line can be used to control radio telegraph or radio telephone transmitters. So that any wire system may be extended by the addition of radio relays and, reciprocally, any radio system may be extended by the addition of wire relays. This process of adding wire and radio links or relays to each other can be carried on to practically any desired extent and should constitute an element in the communication systems of the future under the circumstances previously mentioned. On a moderate scale it is being carried out commercially today in the case of messages from Europe received by the Radio Corporation of America at its receiving stations on Long Island and in New Jersey. From these points the messages are automatically relayed over wire lines to the New York office of the Corporation at Broad Street, where the receiving operators take down the messages by ear, if sent at hand speed, or the messages are automatically written down by ink recorders if received at high speed. A similar transfer of telephone signals to and from wire lines is being demonstrated as a commercial proposition in highly successful fashion by the American Telephone and Telegraph Company in the Avalon-Los Angeles radio toll circuit and in the tests with the steamship *Gloucester* equipped with a radio telephone set, enabling any telephone station in the wire system to be connected with persons on shipboard. It has also been similarly carried out experimentally in Japan through the linking of radio telephone receiving and transmitting stations on the coast with the wire line systems of the country, thereby enabling telephone subscribers to communicate directly in certain cases with persons on shipboard.

Certain countries, such as the United States, are so situated geographically as to serve naturally as important relay centers for intercontinental communications. Communications from Europe to South America, and from Europe to the Far East naturally pass over the United States. In view of the rapid rate at which the power required to bridge a certain distance reliably by radio increases with distance for spans of more than a few thousand miles, it is advantageous to establish relay points in the United States whereby communications from Europe to the regions named will be received in the United States and thence automatically or otherwise relayed to their destinations.

Some doubt may have been entertained by engineers as to the traffic-carrying capacity of the ether for long-distance communication. The figures for long-distance telegraphy can be at least roughly estimated without serious difficulty. We shall assume continuous wave transmission, with an appropriate form of key modulation in sending the dots and dashes, and without any tone modulation whatever. Under these conditions, and taking into account both side bands produced as the result of the actual transmission, it has been found that a speed of 100 words (or 500 letters) per minute corresponds to the occupation of a band of frequencies in the ether roughly 100 cycles wide. This is on the basis that the radio-frequency generator maintains its frequency constant during transmission. We shall also assume that the receiver is sufficiently selective to exclude all signals on frequencies outside of this 100-cycle band. Under these conditions, we may say roughly that on each cycle per second of available ether frequencies we can transmit one word per minute. (It must be noted that there is a correction factor required for reducing theoretical "five letter words" to actual "paid words," but this may be neglected for the purposes of this general discussion.) Assuming further that long-distance traffic will be handled in the range of wave lengths between 6000 meters and 40,000 meters, a reasonable assumption on the basis of present day practise (and also a conservative one), we shall have available a band of ether frequencies of from 50,000 to 7500 cycles per second, or 42,500 cycles in all. Accordingly, we can ultimately transmit at least 42,500 words per minute via radio over long distances, or no less than 61,200,000 words per day. If we extend the range of available wave lengths for long-distance communication below 6000 meters through the further reduction of atmospheric disturbances, if we eliminate one of the side bands resulting from transmission, and if we assume the possibility of using the same wave length for transmission at several points of the earth's surface with directional discrimination between the several transmitters at the receiving station, the already enormous daily message-carrying capacity of the ether will be greatly increased. As a matter of comparison, we may state that the figure of 61,200,000 words per day is roughly 150 times the actual traffic sent across the Atlantic Ocean by cable and radio at the present time. A number of perfectly reasonable requirements must be met by transmitting and receiving stations in order to realize the ultimate capacity mentioned above. The transmitters must have strictly constant generator frequency and must occupy the minimum band of frequencies consistent with their key signaling speed. And the receivers must be highly selective for a correspondingly narrow range of frequencies and yet follow the signals accurately. Even today radio engineers are confident that these results will shortly be obtained by carefully chosen technical expedients.

The nature of world communication makes it international in character. Both wire lines and radio waves know nothing of national boundaries, a fact which is sometimes resented by the nations, particularly during hostilities. It is this essentially international character of long-distance communications, particularly of the unguided variety, which has led to the international regulation of radio communication. In 1912, the

London Radio Convention was agreed to by most of the nations of the world and given force by corresponding national legislation in each case. These regulations of the London Convention were fairly general in character and covered the most essential points only. Thus there was left considerable and proper leeway for each nation to settle its own national problems in communication according to local needs and the nature of local institutions. It would seem that some such policy is wise. That is, where important matters of truly international scope clearly require settlement in the interests of effective communication and to avoid inevitable disputes, international regulation has value in the radio field. Beyond this point, which is defined without much difficulty by the experts in the art, regulation becomes burdensome and tends to retard the progress of the radio art and to discourage initiative. At the present time, an International Radio Conference is being arranged for early in 1922 at which a new and up-to-date set of international regulations will be proposed for adoption. The increasing vogue of radio communication and the capabilities of the more modern apparatus make the task of the International Conference a difficult one. For it is a fact that one technically objectionable transmitter not only lowers the grade of its own service but seriously interferes with many other high-grade transmitters and receivers. The paramount necessity for the maintenance of a reasonably high standard for all transmitters and receivers in the radio art is not paralleled to the same extent in any other field of communication. Indeed this is only one of the many respects in which the practise, both in engineering methods and in traffic handling, differs for unguided communications from that for guided communications. The United States has wisely never adhered to any international convention covering wire or cable communications. On the other hand, its policy has been sympathetic toward international radio regulation within the properly restricted limits previously mentioned.

For the rapid growth of world communication, as far as radio is concerned, the degree of regulation of the art by the various governments should be restricted to the enforcement of the international regulations together with such control of the nationality of the owners and personnel of the radio companies as may be deemed necessary for national security. The entire field of unguided communication is so new and is developing so rapidly that great harm can be done by well-meaning but injudicious legislators and officials. Like all pioneer arts, its successful and speedy development depends on wide freedom of experiment by enterprising investigators and encouragement of effort on the part of wide-awake companies.

There is a type of possible world communication which we have not yet considered in detail but which may well have great significance not only for the individual but also for groups of individuals and governments. This is the broadcasting of telegraph messages or of speech. For broadcasting, there is required a powerful transmitting station located as centrally as possible for the area which it is to serve but with due regard to the most desirable point of origin of the broadcast information. With wire or radio relays to the radio broadcasting station, the former point may be largely neglected. For reception of the broadcast messages, there is required a simple selective and sensitive receiver. For such broadcast services as the furnishing of music or speeches, a loud-speaking telephone receiver is a desirable element of the receiving set. For such broadcast service as the supplying of storm warnings, market reports, and the like, the addition of a loud speaking telephone to the receiving set is not so important.

It has been clearly apparent that rural life has been made vastly more pleasant through the farmer's telephone party line, the various forms of small, inexpensive automobiles, gasoline and electric motors, the motion picture, and the phonograph. The addition of high-grade broadcasting of information, both political and agricultural, and of music or other diversions, would be a further very real boon to those living in the less densely populated regions of the earth. There would no longer be the present discouraging isolation and stagnation which is found in so many peasant communities. Clearly we have here a valuable human asset in potential form. As an adjunct to the government, the church, the press, the theater, and other institutions dealing largely with the public, broadcast radio services should have a remarkable future. We can imagine a time when those living in the most remote hamlet may be as completely in touch with world affairs and as free from the boredom which usually accompanies separation from all forms of instruction and amusement as are those living in the crowded metropolis. And perhaps, they may be even better served in that there is likely to be a more intelligent and less indiscriminate choice of the material which is placed at their disposal through the broadcast services.

World communication in its broad realization will have many important effects; among them, commercial, political, scientific, and personal. The effective conduct of international commerce is slavishly dependent on speedy and reliable communication. Unless information and decisions can be rapidly transmitted from one business house to another, or from the headquarters of a business to its subsidiaries and representatives, the pace of business lags greatly and world commerce is discouraged. This fact has been clearly recognized by the greater commercial nations, and is borne out by the vigorous development of the cables by England and of radio communication. by the United States.

There are many ways in which world communication will have political results. In the white light

of unrestricted publicity through the press, it might be anticipated that the policies of the nations must be chosen with greater consideration for the views of their neighbors, with a resulting decrease in friction and irritation between nations. Furthermore, governments provided with effective international communication are able to deal with each other more directly, and without the possible misunderstandings and nerve-racking delays due to repeated handing on of messages from one representative to another. The public tendencies and views of each nation, its aspirations and its methods will all become more clearly known to the remainder of the world, with the result that sources of disagreement can be recognized at an early stage, and the resulting misunderstandings avoided before it is too late. To the extent that definite knowledge by each nation of the faults and virtues of its neighbors can minimize international fallings out, we may confidently expect world communication to promote world peace.

The effectiveness of the life of the individual is greatly dependent on communication. The swift transmission of intelligence in effect extends his personality to any desired point, and enables him to accomplish in a lifetime, without undue effort, what could never have been hoped for in the past. Coincident with the possibility of keeping in touch with friends, family, and business associates at any distance, we find an increased self-confidence and sense of power in the individual and a broader attitude toward the world and its problems. Nor should we fail to appreciate justly the importance of communication within smaller zones. Presumably men will always find their most vital interests within a region of moderate dimensions, and therefore communication within such regions will be of paramount importance. Having satisfied the primary and most important communication needs of each man's city and its suburbs, world communication will extend his reach, when desired, over nationwide and world-wide zones.

Scientific cooperation, both in research and in practise of engineering, has always been slowed up by the lack of communication between the scientists of the various nations. It is curious to note how frequently the same physical law will have the name of a different discoverer attached to it in each country. And since in general, the discoveries were made not long after each other, they were obviously the result of parallel and needless duplication. The establishment of real clearing houses for scientific information and of vigorous cooperation between the widely scattered scientists of the world waits on world communication for its full attainment.

We have reached the day when the cable carries a message from London to New York and gives the answer in three minutes, when a man speaking in Virginia may be heard in Hawaii or Paris, when practically universal telephone service is available throughout the United States, and when the radio messages from Berlin or Honolulu can be written at high speed in ink in New York. If the governments of the world adopt a highly sympathetic and thoroughly warranted attitude toward world communication, if they foster it by all means in their power and vigorously restrain those who would hamper the growing arts which alone can supply such communication, we may confidently expect that the admirable promise of past achievements will be adequately fulfilled in the universal world communication of the future.

CORROSION OF UNDERGROUND PIPES

In certain sections of the country a very serious condition exists in connection with underground pipe systems, owing to the corrosive action of the soil upon the iron of which the pipe is made. The loss from this cause is so large that the Bureau of Standards has recently undertaken an extensive investigation of the subject with particular reference to the corrosive action of soils on gas and water mains.

In this investigation, the Bureau of Standards has the cooperation of the Bureau of Soils of the Department of Agriculture, the pipe manufacturers, and the public utility companies through the Research Subcommittee of the American Committee on Electrolysis. Forty locations have been selected representing the different kinds of soils to be found throughout the United States and at each locality a number of samples of every kind of iron and steel pipe in commercial use will be buried. Some of these samples will be uncovered from time to time to determine the rate of corrosion. Complete data on the physical and chemical properties of the soil and the pipes will be obtained and extensive laboratory experiments will be conducted to determine the effects of variations and individual characteristics of both soils and pipe materials. Some tests of representative pipe coatings will also be undertaken.

The results of the tests should be of great value in determining the importance of soil corrosion and in selecting the kind of pipe best suited for use in any particular soil. It is expected that considerable data as to the relative rates of corrosion of the different kinds of pipe in the soils under observation will be obtained within 2 or 3 years but the investigation will probably continue over a period of 8 or 10 years. Progress reports will be published from time to time as developments warrant.

A Vacuum-Tube Alternating-Current Potentiometer

BY E. C. WENTE

Research Laboratories of the American Tel. & Tel. Co. and Western Electric Co., Inc., New York, N. Y.

A description is given of an alternating-current potentiometer which is suitable for the measurement of electromotive forces having frequencies up to 10,000 cycles per second. Both the phase and magnitude are read directly from the dial settings.

A special type of a-c. differential galvanometer used in connection with the potentiometer is also described.

IN the investigation of many telephonic and acoustic problems it is necessary to measure very small voltages throughout a wide range of frequencies. Because of the outstanding advantages of the potentiometer method for measuring small electromotive forces it has seemed desirable to improve the means of applying it to this service. Numerous difficulties are encountered, however, in attempting to make use of the common types of alternating-current potentiometer circuits. The electromotive forces set up by stray magnetic fields from air-core inductance coils and the stray currents, which pass through the distributed capacities of the coils or through the capacities to ground of the different parts of the circuit, are sufficient to preclude the use of certain forms of apparatus. The Drysdale potentiometer, although relatively free from these sources of inaccuracies, does not cover the desired frequency range and has the further disadvantage of requiring a considerably greater a-c. input than the usual vacuum tube oscillator will deliver without a special amplifier. The form of a-c. potentiometer, which is here described, has been used successfully throughout the frequency range from 60 to 14,000 cycles per second, and the a-c. power required is so small that a standard type of vacuum-tube oscillator may be used as a source of alternating current.

A further advantage of the potentiometer over most of the other types that have been described is the fact that the readings give the phase and voltage of the measured e. m. f. directly. Since most a-c. potentiometer measurements are used in finding the ratio of electromotive forces, it is more convenient to have the readings given in this form than as the sum of two right angle component voltages.

The success of this type of potentiometer depends on the use of vacuum tubes not merely as amplifiers but as unilateral elements to prevent the undesirable reaction of some parts of the circuit upon others. It is thus possible to control the amplitude and phase of comparatively large currents without any troublesome reaction of the load on the controlling circuit. Special precautions have been taken to reduce the effects of stray magnetic fields and of mutual capacities to a minimum. For the sake of convenience in using this apparatus it has been found desirable to construct a new form of a-c. differential galvanometer and a special phase-shifting rheostat. With the potentiometer as constructed measurements of both voltage and phase may be made by a few simple adjustments, and experience has shown that the results are accurate over a wide range of frequencies.

The Circuit

The complete circuit of the potentiometer is shown in Fig. 1. V_1, V_2 and V_3 are three-element thermionic vacuum tubes of the audion type. The secondary of a transformer is connected to a condenser C, and a resistance, R_c, in series. The input terminals of the vacuum tube, V_1 are connected across the condenser, and those of V_2 across the resistance. The output circuits of these tubes operate into the two transformers T_2 and T_3, the secondary windings of which are connected to two equal resistances, R_1 and R_2, respectively. By means of the sliding contacts, k_1 and k_2, part of the resistance R_1, and part of the resistance, R_2 are shunted across the input of the third vacuum tube. The output of this tube operates into a transformer, the secondary of which is connected to the potentiometer slide wire, R. T is either a telephone receiver or a vibration galvanometer, which serves the purpose of indicating when the drop of potential between d and k is the same in magnitude and phase as the unknown electromotive force V_x.

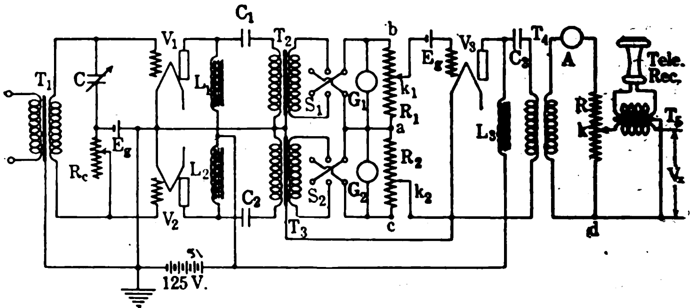

FIG. 1—COMPLETE POTENTIOMETER CIRCUIT

Theory of Operation

If the impedances, R_c and $\dfrac{1}{\omega C}$ are much smaller than the input impedances of the vacuum tubes, the differences of potential across the resistance, R_c, and across the condenser, C, will be practically 90 deg. out of phase. If R_1 and R_2 are equal, the transformers, T_2 and T_3, of identical design, and if the tubes V_1 and V_2, have the same output impedances, the currents in R_1 and R_2 also will be 90 deg. out of phase. By proper adjustment of C and R_c these currents may be

made equal to each other in magnitude. To facilitate this adjustment, one coil of a differential a-c. galvanometer of special design is connected in shunt with R_1, and the other coil in shunt with R_2. By means of the sliding contact, k_1, any fractional part of the voltage drop along R_1, and by means of the sliding contact, k_2, any fractional part of the voltage drop along R_2, may be impressed on the tube, V_3. The two sliding contacts should be rigidly attached to the same dial so that their positions are varied simultaneously. These contacts are placed so that in one extreme position, the input terminals of the tube are connected across R_1 and in the other extreme position across R_2. The phase of the current in R may be varied through 90 deg. by changing the positions of these contacts between the extreme points. By the additional use of the reversing switches the phase may be shifted through 360 deg.

The resistances R_1 and R_2, must be proportioned so that the voltage impressed on the last tube is the same for all positions of the contacts. If $\frac{X}{l}$ is the fractional part of the distance k_1 is moved from a to b, and $\frac{1-x}{l}$ the fractional part of the distance k_2 is moved from c to a, then the resistance between a and k_1 should be

$$R \cos \frac{x}{l} \frac{\pi}{2},$$

and that between k_2 and a,

$$R \sin \frac{x}{l} \frac{\pi}{2}$$

The voltage between k_1 and k_2 will then be

$$I R \cos \frac{x}{l} \frac{\pi}{2} \sin p t + I R \sin \frac{x}{l} \frac{\pi}{2} \cos p t$$

$$= I R \sin \left(p t + \frac{x}{l} \frac{\pi}{2}\right)$$

where $I \sin p t$ and $I \cos p t$ are the currents in R_1 and R_2, respectively. Hence, in this case the magnitude of the voltage between k_1 and k_2 is constant and the scale of phase is linear. This arrangement then provides a convenient way of varying the phase of the output current of the last tube without varying its magnitude.

In making a measurement of the voltage, V_s, the phase of the current in R and the position of the contact, k, are adjusted so that no tone is emitted by the telephone receiver, T. If then I is the current flowing through the resistance, R, the magnitude of this voltage is equal to $r I$, where r is the resistance between the points d and k.

The Phase-Shifting Rheostat

With the slide wires, R_1 and R_2, arranged as shown in Fig. 1, it would be necessary to have 900 points of contact if adjustments for phase were to be made to 1/10 of a degree, as is often necessary for obtaining complete silence in the telephone receiver, T_1. By

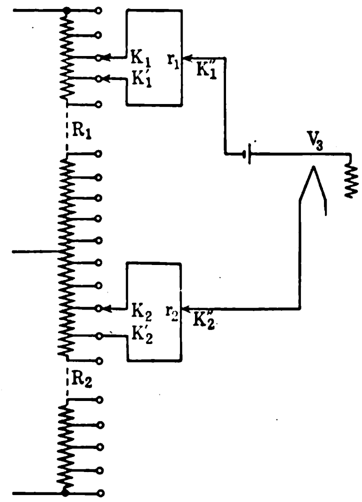

Fig. 2—Double Set of Contacts

the use of a double set of contacts as shown in Fig. 2, the construction is simplified. The sliding connectors, k_1 and k_1', make contact with two adjacent posts. These sliding connectors lead to the terminals of a secondary slide wire resistance, r_1, which should be large compared with that part of R_1 coming between any two adjacent contact posts. The sliding contacts, k_1, k_2, k_1' and k_2' are connected mechanically so that all four are moved simultaneously, likewise k_1'' and k_2''. The dial controlling the former set of contacts then serves for coarse adjustment of phase and that regulating the position of the latter for fine adjustment. In practise it has been found convenient to have 46 contact points on each of R_1 and R_2 so that one step on the first dial shifts the phase through two degrees. With the second dial the phase adjustment may then be made to within a fraction of a degree.

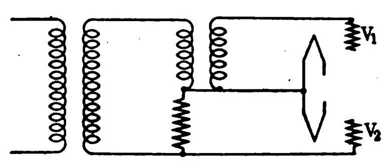

Fig. 3—Diagram of Diferential Galvanometer

The A-C. Differential Galvanometer

In Fig. 1 is shown how the two coils of a differential galvanometer are connected in the circuit to indicate when the potential differences across R_1 and R_2 are equal in magnitude. Most of the different types of instruments described in the literature which might be used for this purpose depend for their action on a heating element. However, hot wire instruments have

to be readjusted frequently, burn out with a very small overload and have a comparatively low sensitivity. In general, they also have a low resistance and so are adapted to comparing currents rather than voltages. An electrodynamic type of differential galvanometer was therefore designed, which gave entirely satisfactory results.

Fig. 3 will make clear the construction of the instrument. To the frame, B, are attached two small shell-type transformers, of which D_1 and D_2 are the primary windings. The secondary windings, consisting of the aluminum rings, S_1 and S_2, *i. e.*, of single short-circuits turns, are rigidly held together by the bar, A, and thus form with the mirror, M, the moving system suspended at P.

When an alternating potential difference is applied to one of the primary coils a force of repulsion will be set up between this coil and the corresponding secondary winding. If then the two transformers are exactly alike and the point of support, P, is midway between the coils, S_1 and S_2, there will be no rotation of the moving system from its normal position whenever the electromotive forces impressed on the primary windings are of the same frequency and are equal in magnitude. The instrument thus affords a convenient method for determining the equality of two voltages of the same frequency.

Neither the impedance nor the sensitivity of this instrument is constant with frequency. But this defect is of no great consequence so long as the use of the instrument is confined to a comparison of voltages of the same frequency. This case, in fact, is the only one where this particular type of differential galvanometer has any practical value. Here, however, it has the following points to commend it. The primary coils may be wound to any desired impedance so that the galvanometer can be adapted for use in circuits carrying either large or small currents. The sensitivity appears to be several times greater than that of the various hot-wire types of instruments. The instrument may be subjected to a very large overload without injury. The moving system has exceptionally good mechanical characteristics, short period and high damping. An advantage of this type of instrument over one that might be constructed on the principle of the ordinary electrodynamometer, is the fact that no lead wires are required for sending current through the coils of the moving system. The mechanical construction is therefore much simpler in this respect.

Sources of Inaccuracies

Since one of the output terminals of a vacuum-tube oscillator is generally either completely grounded, or has a comparatively low impedance to ground, the mutual capacity between the primary and secondary windings of the transformer, T_1, should be small, otherwise the condenser, C, and the resistance, R_c, will not be traversed by the same current. In this case the potential difference across the condenser and the resistance will not necessarily be 90 deg. out of phase. Inaccuracies on this account may be kept small if the transformer has a grounded shield between its windings and if the capacity between this shield and the secondary winding is small compared with the capacity of the condenser, C. In order to have the phase difference of the voltages impressed on the tubes, V_1 and V_2, accurately 90 deg. out of phase the input impedance of these tubes should be large. On this account it is best to use tubes with a low amplification constant.

At low frequencies the impedances of the stopping condensers, C_1 and C_2, may be comparable with the input impedances of the transformers, T_2 and T_3. These condensers should therefore have very nearly equal capacities. For the same reason the impedances of the coils, L_1 and L_2, should be large and have very nearly the same values.

As may be seen from Fig. 1, the resistance, R_2, is grounded at one point whereas R_1 is not. If the mutual capacity between the primary and secondary windings of the transformers, T_2 and T_3, is appreciable, then because of this dissymmetry, the current in R_1 will not be accurately 90 deg. out of phase with the current in R_2, even if the voltages impressed on the primaries of the transformers are 90 deg. out of phase. It is therefore preferable to place a grounded shield between the windings of these transformers. Inaccuracies on account of dissymmetry will not be eliminated altogether by this arrangement, but will be small, if the capacity between the shield and the secondary winding of the transformers is small and balanced.

The resistance, R_1 and R_2, should not be so large that the current through these resistances will be changed appreciably when shunted by the input impedance of the tube, V_3; for this reason this tube should also have a small amplification constant.

The telephone receiver, T, when in use, is necessarily partially grounded; hence, if there is any mutual capacity between the windings of the transformer, T_5, current will flow from the primary winding through the secondary to ground and a false balance will be obtained. It is advantageous, therefore, to use here a transformer with a grounded shield between the windings. If the capacity of the primary winding to this shield is balanced, the current through the receiver, T, will in all cases be equal to zero whenever the drop of potential between K_3 and d is equal to V_x.

A Modification of the Circuit

Instead of a condenser, C, (Fig. 1) a mutual inductance may be used in the manner shown in Fig. 4. It is evident that, theoretically at least, the voltages impressed on the tubes, V_1 and V_2, will be 90 deg. out of phase as in the preceding arrangement. However, this circuit is less desirable because the electromotive

forces impressed on the two tubes, will in practise not be 90 deg. out of phase on account of the distributed capacity in the inductance coils, which cannot be avoided entirely. A further disadvantage on the use of inductance coils in place of a condenser is that stray magnetic fields may induce electromotive forces in other parts of the circuit and thus cause serious errors.

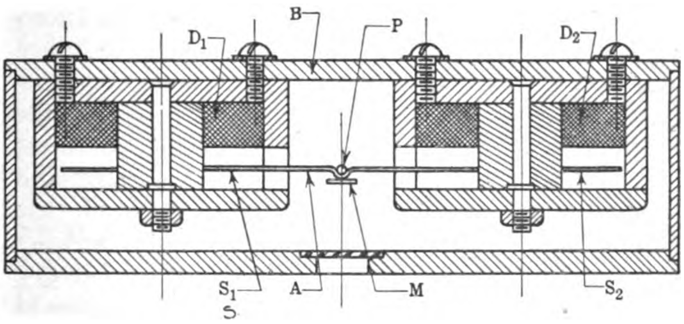

FIG. 4—MUTUAL INDUCTANCE USED IN PLACE OF CONDENSER

MECHANICAL CONSTRUCTION

Fig. 5 shows the general appearance of a form of potentiometer which was constructed on the principle just described. All the electrical parts of the apparatus are placed within a shielded box, to the vulcanite cover of which are attached the control dials and switches. For the various functions of these refer to Fig. 1. Dials 1, control the capacity of the condenser

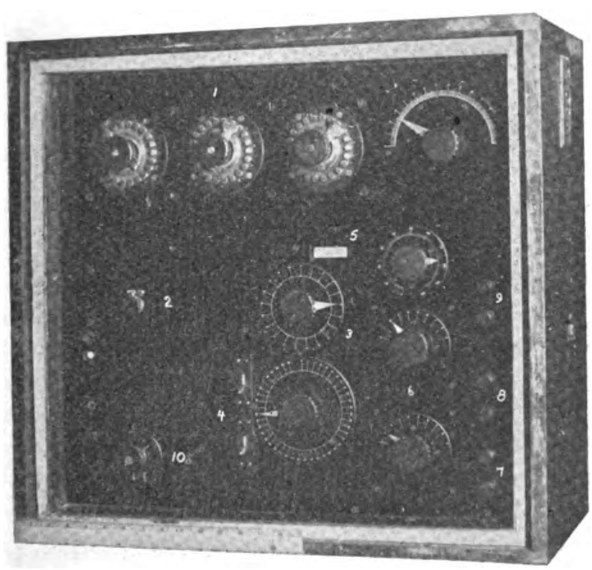

FIG. 5—POTENTIOMETER

C; the maximum value of the capacity of this condenser is 1 microfarad. By means of the switch, 2, R may be given a value of either 1000 or 6000 ohms, the latter being used for frequencies below 200 cyles per second. Coarse and fine adjustments of the phase-shifting rheostat are made by the dials, 3. The reversing switches, 4, correspond to S_1 and S_2 of Fig. 1.

The ground glass window, 5, on which the light reflected from the mirror of the differential galvanometer is brought to a focus, serves to indicate when the voltages across the two coils of the galvanometer are equal in magnitude. A resistance dial, 10, controls the filament currents of the vacuum tubes. Dials, 6, regulate the slide wire resistance and so the potential drop between k_3 and d; the readings of these dials, after a balance has been obtained, thus give the magnitude of the measured e. m. f. To measure the current flowing through the slide wire resistance an a-c. ammeter is connected to the terminals, 7. The measured voltage is brought to the potentiometer through the terminals, 8, and the telephone receiver or vibration galvanometer used in getting a balance is connected at 9.

APPLICATIONS OF THE A-C. POTENTIOMETER

The a-c. potentiometer possesses a number of distinctive advantages over other types of instruments for measuring alternating electromotive forces. One of the most important of these is the fact that its scale is linear, while the deflection of most a-c. measuring instruments, which depend for their action on a heating element or on electrodynamic forces, is proportional to the square of the electromotive force. Thus, since the sensitivity is the same over its whole scale, the potentiometer is particularly well adopted for measuring small electromotive forces on open circuit and in addition it can readily be constructed so as to give precise readings over a wide range of voltages. Electromotive forces ranging from 0.001 to 5 volts may be measured accurately with the potentiometer here described.

The a-c. potentiometer gives the voltage corresponding to the fundamental component only, regardless of the wave form of the electromotive force to be measured. This fact is a distinct advantage in certain classes of measurements, especially where values are to be obtained as a function of the frequency, as in many telephone problems, for, whatever the wave form of the e. m. f. may be, effects due to the higher harmonics are eliminated.

In many alternating-current problems it is of fundamental importance to be able to measure phase. For example, in the study of distortion produced by amplifiers or other circuits in the transmission of currents of complex wave form, it is often necessary to determine the phase relations as well as the comparative magnitudes of the output and input currents at various frequencies. With the a-c. potentiometer here described both quantities are read directly after three simple adjustments.

The instrument is particularly well adapted for determining electromotive forces as a function of frequency, for, the differential galvanometer permits adjustment to be made quickly in going from one frequency to another. Measurements have been made with this instrument and satisfactory results obtained

for frequencies varying from 50 to 14,000 cycles per second.

The compensating potential difference is supplied by means of a slide wire resistance. This arrangement reduces errors on account of capacity to ground to a minimum. Only iron-core transformers and inductances placed within iron cases, are used in the construction of this potentiometer. Stray fields are thus eliminated, which in measurements at acoustic frequencies might have considerable effect on the precision of the apparatus. All the other parts may be enclosed completely in a shielded box. The apparatus is thus entirely protected from outside electrical disturbances.

NOTES FROM THE BUREAU OF STANDARDS

PARIS CONFERENCE ON RADIO REGULATION

During the past summer, delegates representing the leading nations met in Paris to consider certain technical questions concerned with radio communication and to make a report to the next International Communications Conference.

Radio communication is now regulated in accordance with the London Convention of 1912, and the revolutionary developments in radio since that time have made new regulations imperative.

The Inter-Allied Technical Committee, which sat from June 21 to August 22, considered primarily a set of 14 questions prepared by the Preliminary Communications Conference of the five principal powers which met in Washington in 1920. Two delegates of the Department of Commerce were present. One of the fundamental questions was the classification of waves. The final conclusion really adopts two wave classifications, one by types and one by classes.

The Paris conference did not attempt to allocate particular ranges of long waves to particular countries but formulated the technical principles on which such an allocation should be considered by the next International Communications Conference. The technical principles adopted were in brief: (a) the lower frequency waves should be used for the longer distances and the higher frequency waves for the shorter distances; (b) stations situated in the same general locality and working at similar distances should in principle use adjacent frequencies; (c) each nation should use only the smallest possible number of wave lengths necessary to carry on its radio communication, and (d) use should be made of the directional properties of radio whereby the number of communications carried on in a given region may be increased by employing the same frequency a plurality of times. (This last principle was stated in an appendix to the main conclusions on question 10, but is one of the technical principles laid down.)

The conclusions adopted at the Paris Conference are not binding on any of the governments; they are recommendations made by the conference to each of the five governments represented. It is assumed that they will be the basis of discussion and action at the next World Communication Conference.

A brief typewritten summary of the results of the Paris Conference has been prepared, and interested persons may secure a copy by addressing the Bureau.

CONFERENCE WITH AMERICAN ELECTROPLATER'S SOCIETY

Arrangements have been made for a conference in Washington in the near future with an advisory committee representing the American Electroplater's Society. It is planned to hold such conferences about twice a year in order to afford an opportunity for suggestions or criticisms regarding the work and plans of the Bureau upon electrodeposition and the application of the results in commercial practise.

It is interesting to note in this connection that during the month requests for information or assistance upon electrodeposition were received from five different branches of the government service, namely, the Bureau of Engraving and Printing, the the Hydrographic Office, the Coast and Geodetic Survey, the Quartermaster Corps of the War Department, and the Government Printing Office. In each case some assistance was rendered and arrangements made for further cooperation.

Simple Equations for the Lamp Performance

BY H. E. EISENMENGER
New York Edison Company

The paper is concerned with the finding of new empirical equations for the relations between the "fundamental quantities" of incandescent lamps (voltage, efficiency, candle power, life, wattage, current, and resistance). These equations should be simple and should be free from the main drawback of the equations used heretofore, namely, that the reduction from one given value of a certain "fundamental quantity" other than efficiency, to another value, had to be made in two steps, to and from the "normal" value, the normal value being the value corresponding to a certain assumed "normal" efficiency of the lamp. For instance if we wanted to know at what efficiency a lamp will burn under 110 volts if it shows 1.25 watts per c. under 100 volts, we had to find out first at what voltage the lamp is consuming 1.00 watts per c. A number of new equations is given for the voltage-efficiency and the voltage-candle power relations some of them so simple that they do not require evolution. The accuracy is mostly far better than one half of one per cent. The specific difficulties of the problem and the way of overcoming them are pointed out for application to other relations and other lamps than those for which the equations are given in the earlier portion of the paper.

I. Scope and Object of the Investigation

The term "lamp performance" is understood here to mean the way in which the following "fundamental quantities" for incandescent lamps are interrelated: voltage v, candle power c, total watts w, watts per candle (generally, but wrongly called "efficiency") e, ohms r and amperes i.

Volts v, candle power c, and watts per candle e are of prime importance in practise. The relations between efficiency-voltage and voltage-c.p. will be the only ones to be investigated here and the investigation is extended to tungsten vacuum lamps only, but the method devised and explained can be also applied to the other relations (including life l) and to other types of lamps. The object of this article is to establish simple equations for these relations. The questions to be solved are characterized by the following example: A certain lamp, if connected to the voltage v_1, is burning at the efficiency e_1 giving the light intensity c_1 candles; compute the voltage v_2 which will make that lamp burn at efficiency e_2 and the voltage v_2' which will make it emit c_2 candles.

Earlier attempts[1] to find an equation for the lamp performance resulted in exponential equations

$$\frac{e_1}{e_2} = \left(\frac{v_2}{v_1}\right)^g \quad \text{and} \quad \frac{c_1}{c_2} = \left(\frac{v_1}{v_2}\right)^k \qquad (1)$$

where g and k are constants. It was understood that these equations were true only for a very limited percentage of variation of the variables from their "normal" values. (The "normal" values are those which correspond to a certain fixed standard value e_0 of "efficiency," now mostly chosen as one watt per c.)

The next step taken was to make the exponents in the equations (1) variable instead of constant and to make them dependent on the value of the efficiency e referring to a certain standard efficiency e_0. This made it necessary to resolve every operation into two steps taking the reduction to normal efficiency (unity efficiency) or to the corresponding values of the other fundamental quantities for the first step and the reduction from the normal to the desired value as the second. If, for instance, v_1 and e_1 are given and the question is: "What voltage is necessary to make the lamp burn at the efficiency e_2?" we will first have to find what is the "normal voltage" of the respective lamp; in other words what is the voltage at which the lamp will burn, at the "normal efficiency" $e_0 = 1$, using the formula $\frac{e_1}{e_0} = \left(\frac{v_0}{v_1}\right)^{g1}$ The value of g_1 will have to be found from an empirical table or a curve as a function of e_1 Table I[2]. We thus find the normal voltage v_0. The second step is to reduce from v_0 to v_2 by means of the equations $\frac{e_2}{e_0} = \left(\frac{v_0}{v_2}\right)^{g2}$.

where g_2 again will have to be taken from a table and will have a different value from g_1.

This method has two drawbacks. In the first place it is no real reduction of the empirical curve to a mathematical formula; we have only reduced the curve to another (derived) empirical curve, the curve g, by means of a mathematical formula. (The advantage of reducing the original curve to the curve g consists in the fact that the use of the latter curve more effectively smoothes out the little irregularities inherent to any curve based on observations and resulting from inevitable errors of observation, etc., and it permits a

2. The author is indebted to the National Lamp Works of G. E. Co. for the permission to use its empirical curves and tables of lamp performance. (Table I.)

more correct approximation to average values from all observations.)

The second and more serious objection is that this method renders the calculation rather tedious and lengthy as we always have to find the normal voltage (or normal candle power etc., as the case may be) as shown above, although we are not interested in it.

Other methods like those of Cady[3], of Middlekauf and Skogland[4] also necessitate finding the "normal values" and involve even more complicated arithmetical work in the evaluation although they are free from the first named objection.

The writer has endeavored to find formulas first for the two most important relations (that is between voltage and efficiency and between voltage and candle power) which give an easy, quick and direct solution with sufficient accuracy, without the use of tables or curves and without the necessity of computing the "normal value."

As regards accuracy, the aim has been at the start to keep the errors (of the formula with regard to the original curve) within the limits of ± 0.5 per cent for the range of efficiencies from 0.70 to 1.30 watts per *c* for the following reasons: The accuracy of individual observations on the photometer runs somewhere between 1 per cent and 1.5 per cent and even if readings are taken by two different observers and then averaged, the figures obtained have no greater reliability than somewhere between 0.5 and 1 per cent. In addition to this the slide rule operations may be said to result in additional errors somewhere between 0.1 and 0.5 per cent. In the face of these errors of the curve to be represented by the formula it does not seem necessary to limit the accuracy of the formula any closer than to an error of 0.5 per cent. As regards the range of the efficiency within which the formula should be of the sufficient accuracy of 0.5 per cent, work with tungsten vacuum lamps is, for purposes of practise, always confined to the range of efficiency given above, that is from 0.70 to 1.30 watts per *c*.

It will be shown however that the accuracy of most of the formulas is much greater than required above (± 0.5 per cent) and also that the range within which the formulas hold true is much wider than what has been planned at the start.

II. Results

As some readers may be interested in the results and not in the method devised to get these results, the results are anticipated herewith.

1. *Efficiency-Voltage.* The equation for the relation between voltage and efficiency is

$$\frac{v_2}{v_1} = \left(\frac{e_1 - 0.1700}{e_2 - 0.1700} \right)^{0.428} \tag{2}$$

from which

$$v_2 = v_1 \left(\frac{e_1 - 0.1700}{e_2 - 0.1700} \right)^{0.428} \tag{2A}$$

or, if the voltages and one of the efficiencies e_1 is given and the other efficiency e_2 is required

$$e_2 - 0.17 = (e_1 - 0.17) \left(\frac{v_1}{v_2} \right)^{2.336} \tag{3}$$

from which

$$e_2 = (e_1 - 0.17) \left(\frac{v_1}{v_2} \right)^{.336} + 0.17 \tag{3A}$$

From the fact that, with constants as exponents the voltages in these equations occur only in their mutual ratio, it is evident that it no longer makes any difference whether we introduce the voltages as percentages of the (unknown) "normal" voltage or measured in any other unit, for instance in volts. Fig. 1 shows the errors resulting from the application of this formula. To obtain the values of the errors in Fig. 1 and the following curves, the values of Table I have been

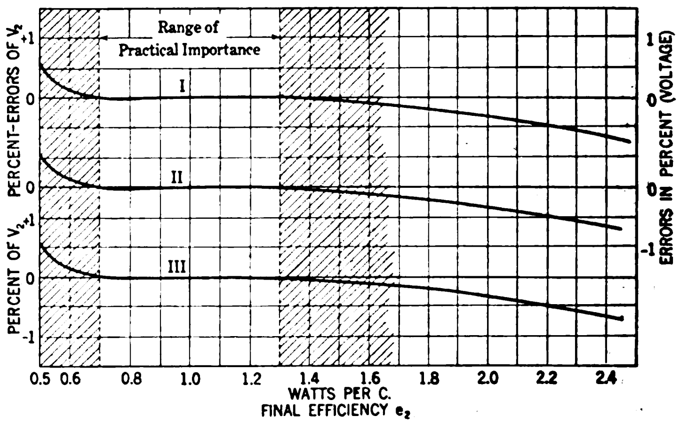

Fig. 1—Error Curves of the Efficiency-Voltage Equation (2)

assumed to be the absolutely correct and accurate ones. The values in this table are the probable values obtained as the averages from a large number of observations on a large number of lamps.

The upper curve of Fig. 1 refers to $e_1 = 0.71$, that is, to reductions from the efficiency $e_1 = 0.71$ to any other efficiency e_2 as given by the abscissa; the second curve refers to $e_1 = 1.00$ that is to reductions from the efficiency 1.00 watt per *c.* to another efficiency e_2, and the third curve refers to $e_1 = 1.31$ watt per *c.* The errors in every one of these three cases remain within much closer limits than has been found necessary above as long as the assumed limits of 0.70 and 1.30 watt per c. (and even much wider ones) are maintained. It may be assumed that with the initial efficiency e_1 anywhere between the values designated by the three curves of Fig. 1 the accuracy will not be essentially smaller than in any one of the three curves.

Example of the Use of this Formula. A lamp is found to be burning at 1.31 watt per c. under 110

3. Cady, *Elec. Review & West. Elec.*, Vol. 59, 1911, page 1092.

4. Middlekauf & Skogland, Transactions Ill. Eng. Soc. 1914, page 744.

volts; how high must the voltage be raised to make the lamp burn at 0.80 watt per c.?

$e_1 = 1.31$ watt per c. $v_1 = 110$ volts

$e_2 = 0.80$ watt per c. $v_2 = ?$

$$\frac{v_2}{v_1} = \left(\frac{e_1 - 0.17}{e_2 - 0.17}\right)^{0.428} = \left(\frac{1.14}{0.63}\right)^{0.428} = 1.2890$$

$$v_2 = 1.2890 \times v_1 = 1.2890 \times 110 \text{ volts} = 141.79 \text{ volts}$$

This however is not the only practical formula for the purpose. The method devised for the derivation of these formulas and described in Chapter III permits, as will be shown there, of developing quite an assortment of formulas. We could get for instance more accurate formulas than the one given, at the price of having a more complicated structure of the formula but as the accuracy of equation (2) is greater than required, these varieties can be left out of considera-

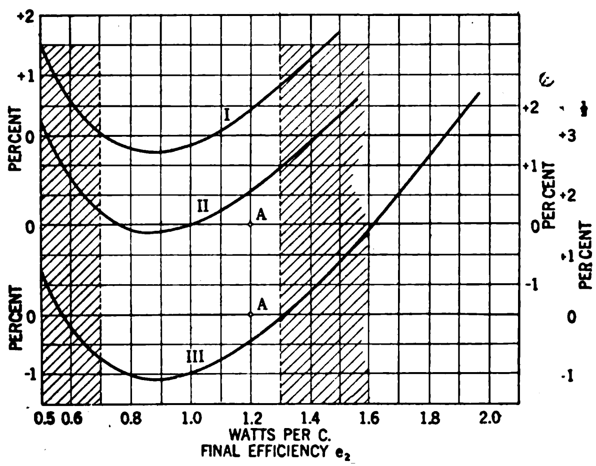

FIG. 2—ERROR CURVES OF THE SIMPLIFIED EQUATION (2B) FOR THE EFFICIENCY-VOLTAGE RELATION

tion. We also can obtain simpler formulas if we are willing to sacrifice a little of the accuracy. Such a relation is

$$\frac{v_2}{v_1} = \frac{e_1}{e_2} \times \frac{e_2 + 1}{e_1 + 1} \qquad \text{(2B)}$$

This equation does not require any involution and no double log slide rule or logarithmic table is necessary for its evaluation. The operations are so simple that they can be quickly made anywhere with nothing but pencil and paper, in some cases even without such help by mental arithmetic alone. The formula contains no constants to be remembered (except unity) and is easy to keep in memory: The ratio of voltages is inversely proportional to the ratio of efficiencies multiplied by a fraction consisting of the direct ratio of the efficiencies with unity added in both the denominator and the numerator.

Fig. 2 shows the error curves for $e_1 = 0.71$, $e_1 = 1.00$ and $e_1 = 1.31$. Error curves for other initial efficiencies can, if required, easily be interpolated by drawing parallel lines to the curves through the respective points of the zero axis, for instance through *A* in curve II or III if the error curve for $e_1 = 1.20$ should be desired. The curves show that the errors are sufficiently small for almost any kind of practical work as they nowhere go substantially beyond one per cent, and only in such cases where efficiencies greater than 1.2 watt per c. are involved do they go substantially beyond 1/2 per cent.

Example: A lamp is burning at an efficiency $e_1 = 1.25$ watt per c. under the voltage $v_1 = 120$ volts; how high must the voltage be raised to burn the lamp at $e_2 = .8$ watt per c.?

$$\frac{v_2}{v_1} = \frac{1.25}{.8} \times \frac{1.8}{2.25}$$

The factors 0.2 and 0.25 cancel out and we get

$$\frac{v_2}{v_1} = \frac{5}{4} \times \frac{9}{9} = \frac{5}{4}$$

from which $v_2 = 5/4 \times 120 = 150$ volts.

With no other known formula would it be possible to solve this problem by mental arithmetic alone. The accurate solution from Table I would be 151.17, or 0.78 per cent greater. This is in accordance with the error curves of Fig. 2.

2. *Voltage-C. P.* The nature of this problem is slightly more complex than the voltage-efficiency problem. The easiest way to understand why this is so, is to examine an example. Let us suppose that we wish to answer the question: If a certain lamp is found to give $C_1 = 100$ candles at $V_1 = 110$ volts, how many candles C_2 will it give at $V_2 = 125$ volts? This problem is indeterminate. The lamp may be a very large one and emit the 100 candles at 110 volts with a more or less red glow, or, on the other extreme, it may be a small lamp burning at great brilliancy under 110 volts. It can be expected that the change of voltage from 110 to 125 volts may effect the candle power differently in the two lamps. Even without going to such extremes, it can be definitely proved from Table I that the problem is indeterminate. To show this, let us first assume that the lamp of the example emits its 100 candles under $v_1 = 110$ volts at an efficiency of 0.90 watt per c. This efficiency e_1 corresponding to c_1 and v_1 will be called "initial efficiency" in the following:

By using Table I we find that the voltage corresponding to 0.90 watt per c. is 105.66 per cent of the normal, and the normal voltage is therefore

$\frac{110}{1.0566} = 104.107$ volts. The light intensity at 0.90 watt per c. is, according to the same source, 121.20 per cent of the normal intensity, so that the "normal" intensity of the lamp of this example is found at $\frac{100}{1.2120} = 82.508$ candles. Raising the voltage to 125 volts means therefore raising it to

$$\frac{125}{104.107} = 120.07 \text{ per cent of the normal voltage}$$

and this percentage of overvoltage corresponds, according to Table I, (interpolation) to 187.62 per cent of the normal intensity or 187.62 per cent of 82.508 candles that is 154.80 candles. The lamp will therefore emit 154.80 candles at 125 volts.[5]

In the same way we find that if the initial efficiency was for instance 1.31 watt per c. instead of 0.90, the intensity at 125 volts would be 158.12 candles or 2.15 per cent higher than in the first case.

This difference is not very great and can be neglected for rough calculations. If we restrict however the permissible errors in c. p. within the limits ± 0.5 per cent, as has been stipulated above, (or if we go outside of the assumed limits of efficiency 0.70 and 1.30) the problem must always state the initial efficiency and every formula for the voltage-candle power relation must of necessity contain the initial efficiency.

On the other hand it is not necessary that the initial efficiency be known with great accuracy, because, as shown in the example, and as will be seen from the formula itself, the influence of the value of the efficiency is a very limited one. If in a certain case it should not be feasible or too troublesome to measure the actual initial efficiency at which the lamp is burning, we have to be content with estimating it by eye-sight from the brilliancy of the filament or by taking the rated efficiency in case the lamp is burning in its regular socket. The error introduced even by a comparatively large error in estimating the initial efficiency will not be great and at any rate smaller than if we leave the initial efficiency out of the formula altogether.

The formula found for the voltage-candle power relation is the following:

$$\frac{c_2}{c_1} = \left(\frac{\frac{v_2}{v_1} - [0.190 + 0.1\,\epsilon_1]}{0.810 - 0.1\,\epsilon_1} \right)^{2.834} \qquad (4)$$

or conversely from this

$$\frac{v_2}{v_1} = (0.810 - 0.1\,\epsilon_1) \left(\frac{c_2}{c_1} \right)^{0.3529} + (0.19 + 0.1\,\epsilon_1) \qquad (5)$$

where $\epsilon_1 = e_1 - 1$ if e_1 is the initial efficiency: ϵ_1 can therefore assume a positive, negative or the zero value.

To restrict the chance of making mistakes in the application of the formula keep in mind that the values of the terms $(0.19 + 0.1\,\epsilon_1)$ and $(0.81 - 0.1\,\epsilon_1)$ which occur in every equation must always add up to unity.

Table II shows how the equations change if the initial efficiency varies in steps of 0.1 watt per c.

5. The secondary efficiency e_2 would be 0.711 watt per c. and is therefore within the assumed range (0.7 to 1.3 watt per c.).

TABLE II

$e_1 = 0.7$	$\epsilon = -0.3$	$\frac{c_2}{c_1} = \left(\frac{\frac{v_2}{v_1} - 0.220}{0.780}\right)^{2.834}$	$\frac{v_2}{v_1} = 0.780\left(\frac{c_2}{c_1}\right)^{0.3529} + 0.220$
$e_1 = 0.8$	$\epsilon = -0.2$	$\frac{c_2}{c_1} = \left(\frac{\frac{v_2}{v_1} - 0.210}{0.790}\right)^{2.834}$	$\frac{v_2}{v_1} = 0.790\left(\frac{c_2}{c_1}\right)^{0.3529} + 0.210$
$e_1 = 0.9$	$\epsilon = -0.1$	$\frac{c_2}{c_1} = \left(\frac{\frac{v_2}{v_1} - 0.200}{0.800}\right)^{2.834}$	$\frac{v_2}{v_1} = 0.800\left(\frac{c_2}{c_1}\right)^{0.3529} + 0.200$
$e_1 = 1.0$	$\epsilon = 0.0$	$\frac{c_2}{c_1} = \left(\frac{\frac{v_2}{v_1} - 0.190}{0.810}\right)^{2.834}$	$\frac{v_2}{v_1} = 0.810\left(\frac{c_2}{c_1}\right)^{0.3529} + 0.190$
$e_1 = 1.1$	$\epsilon = +0.1$	$\frac{c_2}{c_1} = \left(\frac{\frac{v_2}{v_1} - 0.180}{0.820}\right)^{2.834}$	$\frac{v_2}{v_1} = 0.820\left(\frac{c_2}{c_1}\right)^{0.3529} + 0.180$
$e_1 = 1.2$	$\epsilon = +0.2$	$\frac{c_2}{c_1} = \left(\frac{\frac{v_2}{v_1} - 0.170}{0.830}\right)^{2.834}$	$\frac{v_2}{v_1} = 0.830\left(\frac{c_2}{c_1}\right)^{0.3529} + 0.170$
$e_1 = 1.3$	$\epsilon = +0.3$	$\frac{c_2}{c_1} = \left(\frac{\frac{v_2}{v_1} - 0.160}{0.840}\right)^{2.834}$	$\frac{v_2}{v_1} = 0.840\left(\frac{c_2}{c_1}\right)^{0.3529} + 0.160$

Although the constants in the equations of Table II vary over quite a considerable range the values for c_2/c_1 and v_2/v_1 are affected only comparatively slightly

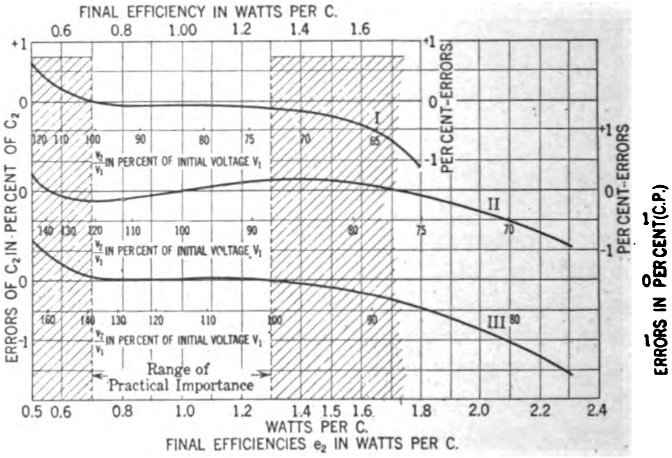

Fig. 3—Error Curves of Equation (4) for the Voltage-C. P. Relation

by these great changes. As we proceed for instance from the top line to the bottom line in the column giving the equations for c_2/c_1 we notice that both the enumerator and the denominator of the fraction are increased by the same amount of 0.01 for every step of the table or by 0.06 between the top and the bottom line. As this amount is not great compared to the

total value of either the numerator or the denominator the effect of the change of the constants on the value of c_2/c_1 is small.

Fig. 3 is the error curve of equation (4) for the three initial efficiencies 0.71, 1.00 and 1.31. Fig. 3 shows

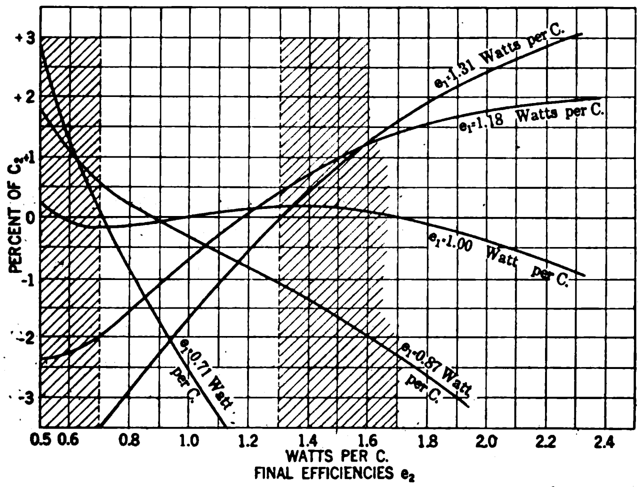

Fig. 4—Error Curves of Equation (4) Neglecting the Correction Factor e_1 to Demonstrate the Influence of this Factor

Compare with Fig. 3

distinctly, as well as Fig. 1, how the error curves, as it were, hug the axis of abscissas in the range for which great accuracy has been aimed at in the construction of the equations, that is in the range of efficiencies between 0.70 and 1.30 watt per c.

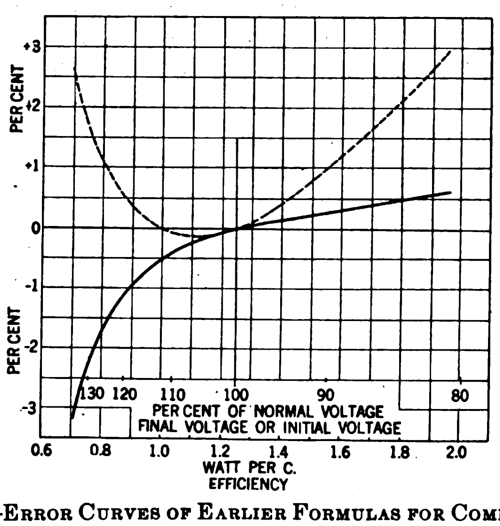

Fig. 5—Error Curves of Earlier Formulas for Comparison

- - - - - $c/c_0 = (v/v_0)^{3.56}$

——— $c/c_0 = (v/v_0)^{3.56}(1 + K)$

where correction factor

$$1 + K = 1 + 0.02\,\frac{v - v_0}{v_0} - 0.5\left(\frac{v - v_0}{v_0}\right)^2$$

Fig. 4 demonstrates the degree of importance of the initial efficiency in a formula for the candle power-voltage relation. In this figure the equation of Table II applying to $e_1 = 1.00$ has been arbitrarily selected and applied to a number of other efficiencies. We get, then, errors as high as 3 and 4 per cent, and even higher, in the range between 0.70 and 1.30 watts per c. The influence of the correction factor in equation (4) (that is, of the members containing ϵ_1) is demonstrated very nicely by Fig. 4, and it can be easily observed how, for instance, the steep error curve for $e_1 = 0.71$ of Fig. 4 is bent by the correction members to follow closely the axis of abscissas in Fig. 3.

Fig. 5 finally shows, for purposes of comparison between the present formula and the older ones, the error curves of the Merrill formula (with constant exponent) and of the Cady formula, both mentioned above. The Middlekauf-Skogland formulas, also referred to above, are extremely accurate, but their use for most practical purposes is out of the question on account of their complicated nature and the numerous operations necessary for their evaluation. The Middlekauf-Skogland equation for the candle power-voltage relation reads

$$\log \frac{v_1}{v_2} = 1.89870 - 1.0282\sqrt{3.41000 - \log c_1/c_0}$$

or conversely:

$$\log \frac{c_1}{c_0} = -9.946\left(\log \frac{v_1}{v_0}\right)^2 + 3.592 \log v_1/v_0$$

and, as stated above, requires reduction in two steps, to and from the "normal" the same as the other older formulas.

III. Derivation of the Equations

The following description of the methods applied for finding the equations may be useful to those who desire to find equations for the relations between the "fundamental quantities"[6] other than the efficiency-voltage and the candle power-voltage relations. It will also be of use if, as the art of lampmaking advances, the two relations just referred to should change and the respective curves alter their shape so that the constants in the equations will also have to be adjusted. The same applies to the establishment of the equations for other types of lamps, for instance the type C Mazda (gasfilled) lamps.

Fig. 6 shows a curve representing in the customary way the empirical relation between the intensity of light emitted as ordinate and the voltage as abscissa. It will be noted that neither the candle power nor the voltage is given in the usual units, but as percentages of certain "normal" values of the voltage and the candle power, respectively; that is, the units are the voltage v_0 at which the lamp has to burn if it shall have a certain "normal" efficiency e_0 (for type B or vacuum tungsten lamps at present generally assumed to be one watt per c.) and the candle power c_0 which the lamp emits if burning at that normal efficiency. The

6. See the introductory words of this paper.

same applies to all the other "fundamental quantities." If therefore v, c, w, i, and r designate the voltage in volts, intensity in candles, energy in watts, current in amperes, and resistance in ohms, respectively, the length of the abscissas and ordinates of the respective curves do not represent v, c, w, etc., but v/c_0, c/c_0, w/w_0 etc. where the index $_0$ designates here, and in the following, the normal value.

1. *Voltage-Efficiency Curve.* The empirical curve between v/v_0 (percentage volts of the normal voltage) as abscissas and the efficiencies as ordinates resembles roughly an equilateral hyperbola corresponding to the equation $v/v_0 \cdot e = K$. In order to make a closer fit between the given curve and the equation the latter has been extended by shifting the asymptotes parallel to themselves away from the axes

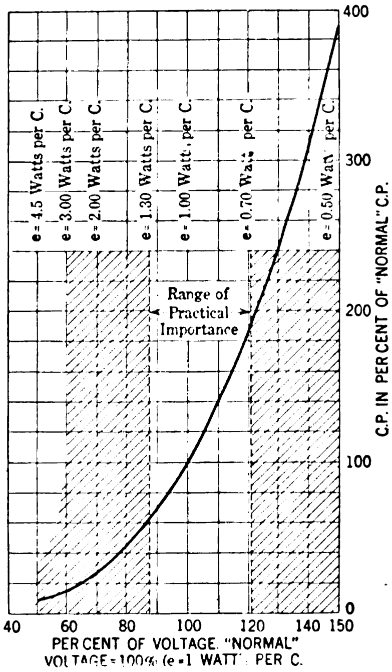

FIG. 6—VOLTAGE-C.P. CURVE

of co-ordinates, and by choosing a hyperbola of the nth order instead of an equilateral one. The equation then becomes

$$(v/v_0 - a)\,(e - b)^n = K \tag{6}$$

This equation contains four unknown constants a, b, n, and K, besides the given normal voltage of the lamp, which is the unit of the voltages in this formula. Obviously the four constants will assume different values if the units chosen for v and e vary.

As explained above we wish to make the equation independent of the unit chosen for the voltage, so that the use of the formula for reducing from v_1 to v_2 does not necessitate computing the "normal" value v_0. This can be done by transforming the equation in such a way that the term for the voltage v does not occur otherwise than in a ratio between two voltages other than v_0.

Applying equation (6) to a given point I (e_I, v_I) permits of expressing v_I/v_0 in terms of e_I and of the constants. The same can be done for another point II of the empirical curve with the co-ordinates (e_{II}, v_{II}). By dividing one of these two equations by the other one v_0 cancels out and we get

$$\frac{v_I}{v_{II}} = \frac{\dfrac{1}{(e_I - b)^n} + \dfrac{a}{K}}{\dfrac{1}{(e_{II} - b)^n} + \dfrac{a}{K}} \tag{7}$$

Voltages occur in this equation only as mutual ratios and the equation holds good therefore for any unit voltage, consequently also for the customary unit of the volt.

This equation contains four constants a, b, n, and K, and the corresponding curve can therefore by proper choice of the numerical values of these constants be made to pass through any desired four points of the empirical curve.

Trials demonstrated at once that the accuracy of this equation is far greater than that at which we are aiming (1/2 per cent) and therefore the formula can be simplified by assuming one of the constants at a convenient value ($a = 0$, $b = 0$, or $n = 1$). The three remaining constants of the simplified equation can then be found in the ordinary manner by applying the equation to three different points and solving for the constants.

Carrying out the first one of these possibilities ($a = 0$), that means letting one of the two asymptotes coincide with the v-axis, and applying the equation to three points at adequate distances within the range for which the equation is to be used, for instance at $e_1 = 1.230$, $e_2 = 1.000$, and $e_3 = 0.730$ watt per c., results, after proper reduction, in

$$\frac{v_2}{v_1} = \left(\frac{e_1 - 0.170}{e_2 - 0.170} \right)^{0.428} \tag{8}$$

identical with (2)

Following the second one of the above named possibilities and letting $n = 1$ we get, after proper reduction,

$$\frac{v_2}{v_1} = \frac{e_2 + 1.812}{e_1 + 1.812} \cdot \frac{e_1 + 0.143}{e_2 + 0.143} \tag{9}$$

This formula which is still too complicated for practical use can be simplified in the following manner. Each one of the two fractions on the right hand side of the equation contains a constant. Increasing this constant has the effect that the value of the respective fraction changes in such a manner that it approaches the unit and vice versa. Whether this means a decrease or an increase in the value of the fraction depends on whether the fraction is greater than or less than 1. Obviously one of the two fractions is greater than the unit and the other one smaller than the unit. Therefore, if we decrease the value of the constant in both fractions, the changes in the values of the fractions

will be of opposite direction and have the tendency to counteract each other in the product of the two fractions. There exists therefore the possibility of simplifying formula (**9**) by reducing the constants over a rather wide range to convenient values, 1 or 0 respectively with a comparatively small reduction in the accuracy. Indeed formula (2B) which has been derived from (**9**) in this manner shows still a good error curve (Fig. 2).

2. *Voltage-C. P. Curve.* The empirical voltage-c. p. curve (Fig. 6) has a shape suggesting a parabola $y = A\, x^m$ where x is the voltage in units of the normal voltage v_0 and y is the candle power in units of the normal candle power.

$$c/c_0 = A\,(v/v_0)^m \qquad \textbf{(10)}$$

Moving again the apex of the parabola away from the origin of coordinates in order to get the possibility of having the parabola pass through a greater number of points of the empirical curve we get

$$\frac{c}{c_0} - b = A\left(\frac{v}{v_0} - a\right)^m$$

or

$$\frac{1}{A}\,\frac{c}{c_0} = \left(\frac{v}{v_0} - a\right)^m + \frac{b}{A} \qquad \textbf{(11)}$$

Here again we wish to get the equation free from the "normal" values c_0 and v_0. We can do this, as far as c_0 is concerned, by the same method as has been applied in the previous section for the elimination of v_0 in the voltage-efficiency relation, but this method is not applicable to the present equation for the elimination of v_0.

It has been shown above that the relation between candle power and voltage cannot be stated with the desired degree of accuracy without introducing the initial efficiency e_1. It is therefore necessary that this efficiency e_1 appears in the formula for the candle power-voltage relation.

In order to free equation (11) from v_0 and at the same time to introduce e_1 we first eliminate c_0 as described above and write the result as follows:

$$\frac{c_2}{c_1} = \frac{\left(\frac{v_1}{v_0}\cdot\frac{v_2}{v_1} - a\right)^m + \frac{b}{A}}{\left(\frac{v_1}{v_0} - a\right)^m + \frac{b}{A}} \qquad \textbf{(11A)}$$

Then we substitute equation (**9**) into (**11a**) writing the former as follows: (remembering that $e_0 = 1$)

$$\frac{v_1}{v_0} = \frac{e_1 + 1.812}{e_0 + 1.812}\cdot\frac{e_0 + 0.143}{e_1 + 0.143}$$

$$= 0.4065\,\frac{e_1 + 1.812}{e_1 + 0.143} \qquad \textbf{(12)}$$

This substitution results in

$$\frac{c_2}{c_1} = \frac{\left(0.4065\,\frac{e_1 + 1.812}{e_1 + 0.143}\cdot\frac{v_2}{v_1} - a\right)^m + \frac{b}{A}}{\left(0.4065\,\frac{e_1 + 1.812}{e_1 + 0.143} - a\right)^m + \frac{b}{A}} \qquad \textbf{(13)}$$

This formula would be unnecessarily accurate and we have again the choice how to simplify it for practical use by selecting certain ones of the constants at convenient values at the expense of the accuracy of the formula.

If we let $b = 0$, that is we shift only the vertical or c/c_0 axis but not the axis of v/v_0 we get after proper reduction:

$$\frac{c_2}{c_1} = \left\{\frac{\frac{v_2}{v_1} - 2.460\,\frac{e_1 + 0.143}{e_1 + 1.812}\,a}{1 - 2.460\,\frac{e_1 + 0.143}{e_1 + 1.812}\,a}\right\}^m \qquad \textbf{(14)}$$

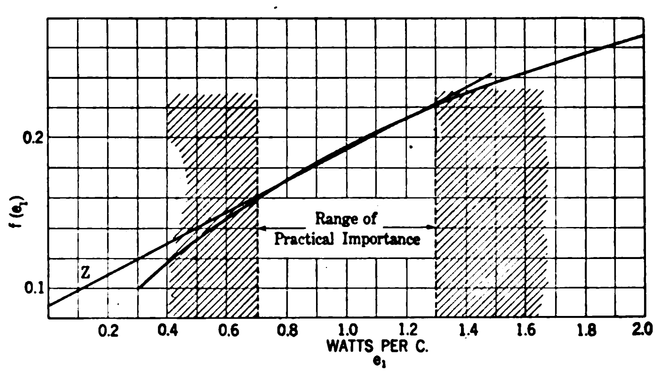

Fig. 7—Approximation of $f\,(e_1)$ by a Straight Line

This formula is now applied in the usual manner to three points of suitable location or in other words to two different sets of c_2/c_1 and the two constants a and m are thus evaluated as 0.1927 and 2.834 respectively. With these values substituted equation (**14**) changes into

$$\frac{c_2}{c_1} = \left[\frac{\frac{v_2}{v_1} - f\,(e_1)}{1 - f\,(e_1)}\right]^{2.834} \qquad \textbf{(15)}$$

where

$$f\,(e_1) = 0.474\,\frac{e_1 + 0.143}{e_1 + 1.812} \qquad \textbf{(16)}$$

This equation requires further simplification in order to be of practical usefulness. If we plot the values of $f\,(e_1)$ against e_1 (Fig. 7) we see in the first place that $f\,(e_1)$ is always small as compared to the members from which it is to be subtracted in equation (**15**). Since moreover $f\,(e_1)$ is to be subtracted from both the enumerator and the denominator of the fraction in equation (**15**) it follows that even comparatively large inaccuracies in the value of $f\,(e_1)$ will

result in but small errors of c_2/c_1. We can therefore replace the curve in Fig. 7 by the straight line $z\,z$ and as the errors introduced into $f(e_1)$ by that simplification are small within the range of practical usefulness ($e_1 = 0.70$ to $e_1 = 1.30$) we will practically not change the accuracy of equation (**15**) by that alteration.

The equation of the straight line $z\,z$, as can be easily seen, is $z = 0.089 + 0.103\,e_1$. Substituting this for $f(e_1)$ in (**15**) leads to

$$\frac{c_2}{c_1} = \left\{ \frac{\frac{v_2}{v_1} - 0.089 - 0.103\,e_1}{0.911 - 0.103\,e_1} \right\}^{2.834} \qquad (\mathbf{17})$$

or setting $e_1 = 1 + \epsilon_1$

$$\frac{c_2}{c_1} = \left\{ \frac{\frac{v_2}{v_1} - 0.192 - 0.103\,\epsilon_1}{0.808 - 0.103\,\epsilon_1} \right\}^{2.834} \qquad (\mathbf{18})$$

Again we can, without essential impairment of the accuracy, introduce round figures for the constants and write

$$\frac{c_2}{c_1} = \left\{ \frac{\frac{v_2}{v_1} - [\,0.190 + 0.1\,\epsilon_1\,]}{0.810 - .1\,\epsilon_1} \right\}^{2.834} \qquad (\mathbf{19})$$

which is the final formula and identical with equation (4) and the equations of Table II. The errors are represented by the error curve Fig. 3.

Application of Electricity in Processes Leading up to Surface and Subsurface Printing

BY CARL F. SCOTT

Mgr. Apparatus Dept., Sprague Electric Works, New York, N. Y.

Introductory

The data presented herewith have been prepared as part of a report on "Electric Power in the Printing Industry." For the purpose of this report the printing industry has been divided into two general classes as follows:

A. Raised surface or typographic printing, including stereotype printing (newspaper), electrotype printing (magazine and book work), and printing directly from the type forms.

B. Surface and subsurface printing.

This paper refers to motor drive and other electrical applications subsidiary to surface and subsurface printing. This class may be divided as follows:

1. Surface or planographic printing, or lithography.
   - (a) Stone lithographic printing (maps, labels, etc.)
   - (b) Rotary litho printing on zinc or aluminum plates (posters, calendars, labels, etc.)
   - (c) Offset printing (fine art reproductions).
2. Subsurface printing.
   - (a) Engraving.
     - (1) Cards and letterheads (die press work)
     - (2) Steelplate engraving (paper money, bonds, stock certificates, postage stamps, etc.)
   - (b) Rotogravure process (illustrated sections of Sunday newspapers).

Lithography

Commercial lithography today is of three general classes: (1) Work done on flatbed presses, where the impression is taken directly from the lithographic stone, whose surface has been prepared and on which the designs have been impressed; (2) work done on rotary presses where the impression is taken directly from a curved plate of zinc or aluminum on whose surface the designs have been impressed in a manner similar to the designs on stone; (3) work done on rotary offset presses, where the impression is taken from a curved metal plate to a rubber blanket secured to an adjacent cylinder and from this rubber cylinder imprinted on the paper.

The art and practise of lithography is based on the well-known fact that oil and water do not mix. The art was discovered, or invented, over a hundred years ago by a Bavarian, Senefelder, who, though lacking the modern mechanical and photographic aids, seems to have practically perfected the art, so that it stands as one of the few arts that came into being almost full-grown.

Senefelder discovered that a certain kind of limestone would absorb or retain on its surface both water and certain oily or greasy inks or crayons. He drew his designs in greasy inks on the level and polished or slightly roughened (grained) surface of the stone, then coated the whole with a thin film of water. Paper was pressed against the stone in a hand press and a picture so made, following which the stone was repeatedly reinked, the oily ink merely adhering to the design, and not at all to the wet or undrawn portion, so that many proofs or reproductions of the original could be made.

This is a very crude description of the rudiments of the early process. The chief improvements since Senefelder's day are the transfer process, photo-lithography, multicolor process, offset process, and mechanical improvements in machinery.

Early lithography was largely used for the repro-

duction of artists' drawings or paintings, and the number of copies desired was few. The work was done on hand presses, and six hundred copies a day was fast work. Today lithography is an extensive and growing industry, unable to meet the country-wide demand for commerical illustrative work in natural colors.

Stone litho presses give the finest results, but print slowly, 1200 to 1500 sheets per hour, and are best adapted to coated paper.

Rotary litho presses do similar work of not quite so high a grade, but at a higher rate of speed, 1800 to 6000 per hour, and in two or more colors at one passage of the sheets, whereas stone presses print only one color at a time. Some rotary presses constructed by the American Lithographic Company printed in six colors on one side and black (type matter) on the reverse.

Rotary offset presses are used chiefly with rough or uncoated stock and produce effects in tone, texture and shading at high speed, as fast as the straight rotary presses. Recently, successful work has been done with coated paper on offset presses.

Motor Requirements of Lithographic Presses

Stone Presses. These presses involve the transfer of the rotary motion of the driving pulley into the reciprocating movement of the bed that carries the stone. A crank movement is employed, with rack and gear. The bed is supported on anti-friction rollers. The load is due to the gear and bearing friction, and to the pressure between the impression cylinder and the stone. The load fluctuates with each reversal of the bed, and increases with increasing speed somewhat faster than the speed. Phase-wound a-c. motors and compound-wound d-c. motors are recommended. Frequent starting and stopping is required. Constant-speed motors are sometimes employed, where a fixed rather low speed of printing is satisfactory. The power requirements of stone presses vary from 2 to 7½ h. p. As commercially constructed, belt drive is employed and rather low-speed motors are necessary. A reverse-point at low-speed is desirable for "backing up".

Rotary Litho Presses. The power requirements of both direct-rotary and rotary-offset presses are similar. The motion is a continuous rotary one, and the load is uniform, varying with the speed at a little faster rate than the speed increases, and varying also with the viscosity of the ink and the impression pressure. These presses are very often fitted with automatic feeders, and should the sheet of paper, as it is fed from the pile into the press, jam the mechanism, it is essential that the press be stopped quickly. This is accomplished by a "feeder-trip" switch which opens the line contactor on the motor controller. A variation involves the automatic slowing down rather than stopping when the feeder jams. A dynamic brake is necessary; on a-c. motors a solenoid brake or its equivalent is usually fitted to the motor shaft.

Both d-c. and a-c. motors are successfully used on litho presses, the a-c. motors having phase-wound rotors, and adapted to run continuously at any speed between full speed and half speed; and the d-c. motors being adapted to an equal range of 2 : 1, this being

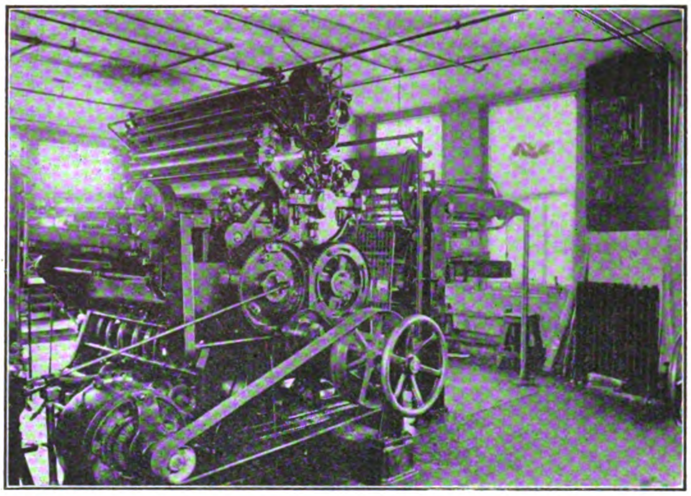

Fig. 1—Rotary Offset Press With Motor Drive. The Push-Button Operated Controller is on the Wall

preferably a combination of about 35 per cent reduction by armature control and about 40 per cent increase by field control. Frequent jogging or "inching" is required during the make-ready periods. A back-up is occasionally, but seldom used. As these presses are sheet-fed, they do not require a special very low speed for "threading-in", as do roll or web-fed rotary

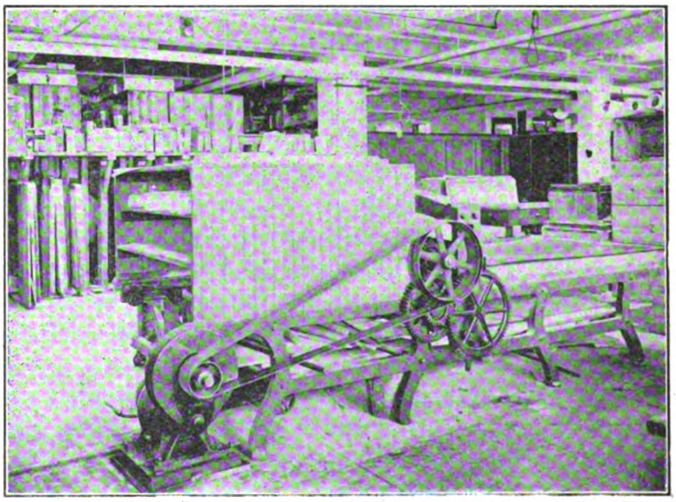

Fig. 2—Litho Transfer Press Equipped With Back-Geared Motor

presses. Power requirements vary with the size of the sheet, number of colors, and speed of production from 2 to 15 h. p.

In the processes leading up to lithographic printing, comparatively little machinery is employed, compared to stereotype or electrotype printing. There are today

a number of different processes employed in reproducing the original drawings on the stone or metal plate. In some of the processes photography is employed, in others not. In one process, the straight lithographic, the artist makes his original drawing with ink or crayons on a lithographic stone. This drawing is used as a master. For actual printing the design is reproduced, either on another stone (sometimes several times on one large stone) or on a metal plate, by the transfer process. A sheet of thin specially prepared paper, called transfer paper, is laid over the original and rolled down to close contact in a transfer press. It is then carefully removed, carrying with it the design reversed. This transfer paper is then laid down on the printing stone or plate and rolled into contact with it, the transfer press being again used. After this the artist goes over the transfer sheet, working on the back of the paper with knife and stipple to get a perfect reproduction. The registering is important, as the design may require printing in many colors on different stones or plates, which must register in final printing. The paper is then moistened and removed, and the design remaining on the stone or plate is fixed by a solution of nitric acid and gum-water.

The smaller transfer presses are hand-operated, the larger ones motor-driven.

Motor-driven transfer presses take from one to three h. p. The operation involves a rack-and-pinion movement for moving the stone carrying the transfer paper under a roller and back again. As the bed can readily be moved by hand when the impression is off, a constant-speed, nonreversing motor is sometimes employed, the motor being stopped at the end of the travel of the bed, the impression lifted by a lever, and the bed returned by turning a hand crank.

A better application is that of a reversible motor with a spring-return reversible controller—that is, a controller which returns to the off position whenever the operator releases the handle. Limit switches at either end of travel are a valuable precaution. The reversible motor allows of taking an impression each way. The load is not fully applied till after the motor starts. Back-geared motors will usually be needed, because of the low speed of the driving pulley, which turns not much faster than a man would turn a crank— 50 to 100 revolutions per minute.

In photo-lithography, the original is photographed on a glass or film negative and a print made from this directly on the stone or plate, the surface of the latter having been sensitized with chromate of potash, which develops out as in ordinary photography, and which is further fixed with the proper solution. In photo-lithography screens are interposed to give fine dots or cross-lines to aid in bringing out the final design in form to receive and hold the ink. In photo-lithography in colors, color-screens are used, so that several negatives can be made, each with the proper portions brought out which are to receive the particular color, there being as many stones or plates as there are colors to be used.

Electricity for lighting in the lithographic process is of great importance. There must be arc or incandescent lamps for the cameras used in photography. There must be light for the artist of just that value which enables him to select his colors and touch up his drawings properly.

In the preparation of the stone, machinery is employed. Stones were formerly polished by hand, with pumice-stone blocks and fine sand or ground flint. The stone-shaving machine described below first came into use to be followed by a stone-grinding machine, employing a polishing or grinding wheel in the form of a stone revolving on a vertical shaft and requiring 3 to 5 h. p. for operation. Because of uneven work and a tendency to scratch on the grinder, the stone-planing machine has come back into favor, except for small stones where a flat, revolving grind-stone is used. The stone-shaver has a screw-driven reciprocating bed, which carries the stone under a knife that takes off a very thin cut at each forward stroke.

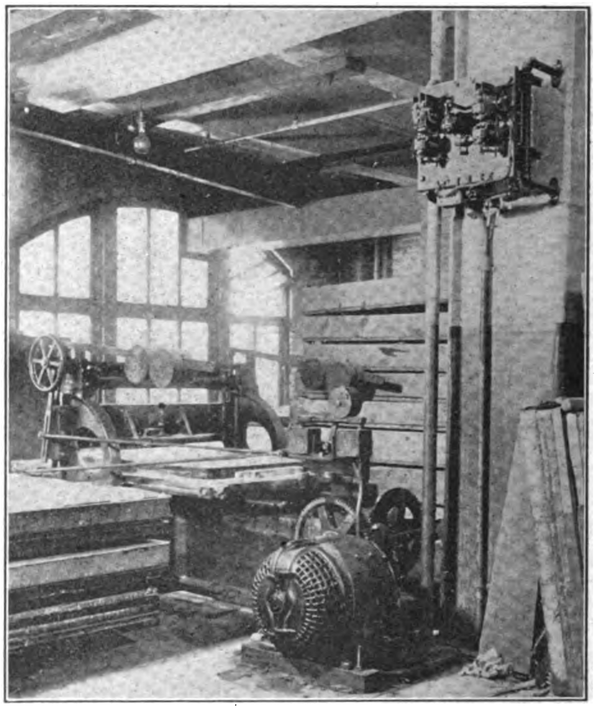

Fig. 3—Stone-Planing Machine Equipped With Direct-Geared Motor and Automatic Reversing Controller

The operation of the stone-planer is not unlike that of a metal-planer. The machine bed carrying the stone is driven back and forth under a cutting knife. the return stroke being preferably at a speed 75 per cent faster than the cutting stroke. The process is automatically repeated till the work is accomplished; hence means for automatically reversing the bed is necessary. The stone-planer may be driven by either alternating or direct-current motors. If alternating, a two-speed (pole changing) motor may be used, with

high-speed connections on the reverse, or, if the time element is not important, the quick return may be dispensed with and a single-speed motor used. Direct-current motors should be compound-wound, and preferably capable of 75 per cent increase in speed by field control in one step. The bed motion of the planer is that of a screw and traveling nut. The motor is preferably geared to the driving-shaft, and a controller for reversing the motor and cutting in the high speed on reverse should be connected to the bed motion in such manner as to be actuated by the bed travel and throw over to reverse position automatically. Either the main control switch or a master controller may be so used.

The zinc or aluminum plates used on rotary litho presses are thin enough to be bent readily to the curvature of the press cylinders and elastic enough to flatten out on removal. The plates are prepared for use by graining, a process in which the plates are set in a wooden box which is given a system of horizontal vibrations by motive power from a ½-h. p. constant-speed, continuous-running low-speed motor, so as to keep in motion a quantity of very fine balls of glass, steel or marble mixed with powdered flint, which roughen up the plate surface. The same process is used to regrain the plates after the run has been made, to prepare them for new work.

Closely allied to lithography are three processes needed to complete certain classes of work, especially fancy colored labels, such as cigar labels. Cigar labels are lithographed on stone, the original design being reproduced many times on the stone by repeated transfers, so that the finished sheet carries several hundred labels. This sheet requires bronzing, embossing and cutting, all of which are machine processes.

A bronzing machine is one in which lithographed sheets are coated with bronze dust, which adheres only to those portions of the design which have previously been printed in a special bronze-colored oily ink—namely those portions which are to have a "gold" appearance in the finished product. The sheets are fed into the machine as into a printing press, and bronze dust is distributed over them by a revolving brush. The dust does not adhere to the colored (non-bronze) portions of the design, but its presence on the bronzed portions gives a luster not obtainable from the ink itself.

The load imposed on the driving motor of a bronzing machine is uniform, the torque required at different speeds being substantially constant. The smaller bronzers are run at constant speeds, the larger ones at varying speeds. Direct-current motors with armature control and polyphase motors with wound rotors operate satisfactorily in this application. The service is non-reversing, requires infrequent starting and stoping, and the speed range is less than 2:1. Several bronzers are so built as to require a separate small constant-speed motor for driving an exhauster. Bronzers take from ½ to 3 h. p. Though generally individually driven, they are sometimes driven by the printing press on which the sheets have been printed, so as to synchronize with the presses and complete the printing and bronzing in substantially a continuous operation. This is accomplished by a chain drive extending between the two machines, and a delivery attachment on the press which feeds into the bronzer.

The embossing presses for this work have dies which register with those portions of the design which are to be raised. The sheets are fed into an embosser as into a printing press, and as each sheet comes under the platens or dies, some of which are usually heated, it is subjected to pressure like that of the steel sheets in a forming press; and the finished sheet is then delivered with the designs raised as desired. The pressure is applied either by a crank or eccentric movement or by toggles, power being supplied by a

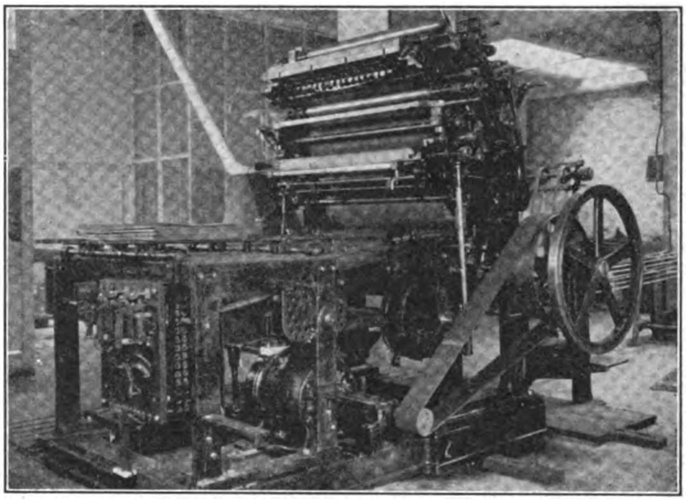

Fig. 4—Rotary Metal Decorating Press Equipped With D-C. Motor and Push-Button Operated Controller

motor of from 2 to 15 h. p., depending on the size and pressure. A large flywheel on the embosser takes up the load at the instant of applying the pressure.

The operation of the machine is not dissimilar to a metal punch press. The starting effort is involved chiefly in accelerating the flywheel, as the embossing work proper is done by throwing in a clutch after the motor is up to speed. Hence the motor speed control does not involve jogging or dynamic brake, but it does involve a speed range of 1½:1 or 2:1, as the number of sheets per minute which can be fed into the embosser will vary with the stock, size, grade, etc. On a-c., motors with phase-wound rotors have been successfully employed, and on d-c., armature control can be used, though field control is usually preferred. Belt drive is almost always employed.

The cutting machines in a lithographic plant may be straight power cutters (guillotine cutters), as used for cutting sheets in piles in all kinds of printing and paper-product manufactures, or cutters fitted with

cutting dies of special design, such as are obviously required to give the conventional shape to cigar labels. The operation of these die cutting machines is very similar in principle to that of the embosser, but less pressure is required and relatively smaller motors are needed and the work is all done at one speed.

In printing on tin plate a press called a metal-decorating machine is used, the process being essentially a surface printing process, in which the printed sheets are given a coating to receive the printing. The work must obviously be done at low speeds, as tin plate cannot be fed as fast as paper sheets. But little machinery is used in the process aside from the press itself, which may take three to five h. p., and the forming and cutting machines which produce the metal container from the flat sheet. After printing, the sheets are varnished and baked to fix the ink.

SUBSURFACE PRINTING

Steel Plate Engraving

The Process. The first engraving was done by skilled artists, who depicted their subject by cutting into a soft steel plate with a fine hardened tool. Today after hundreds of years, the process continues to depend on the skill of the engraver. Prints were made directly from the early plates. They were almost all pictures, and a few copies were needed. Today engraving is a specialized commerical enterprise and thousands of imprints are required. Means have been devised for reproducing the plates and for printing from copies at high speed—relatively high speed, that is, for the speed of plate presses is less than of type or half tone presses or offset presses.

The reproduction of the original plate is carried out in two ways: In the first processes the original plate is hardened and a soft plate is pressed into its depressions. This soft plate is then hardened, and still another plate is pressed over its raised lines. Finally, this last plate is hardened and used for printing. The process is called "transferring" and requires a very powerful hydraulic press. The plates actually used for printing—as many as may be required—are left flat or bent to a curve, according as they are to be used on flat-plate or rotary presses.

The second process, the "electrolytic", involves the filling in of the engraved lines of the original with a copper coating, which is gradually reinforced till it becomes a solid plate, called the "alto." The surface of the original is of course treated to prevent adhering of the copper deposit. From the alto, also by electrolytic process, the "basso," is made, from which the actual printing is done. The electrolytic process employs a 6/12-volt plating generator, of 1000 to 3500-ampere capacity, depending on the amount of work to be done.

Engraving is used by our government for all forms of paper currency; bonds and all government securities; postage stamps; letterheads and important business forms. It is used by the commercial firms engaged in similar work—for stock certificates, bonds, and all negotiable instruments where protection against counterfeiting is of importance.

A simpler form of engraving, involving less process work, is that employed for business cards, invitations, announcements, letterheads, etc. (Die Presses).

The printing process involves inking, wiping or polishing; taking the impression; drying and removal.

The simplest power-operated engraving press is the electrified hand press, used by the Bureau of Engraving and Printing. These presses take a 9 by 13 sheet, are operated by a ¾-h. p., 1350-rev. per min., compound, constant-speed, reversible d-c. motor, and print about 12 sheets a minute.

The next important engraving press is the continuous-feed power-plate press, in which four plates, each taking a 20 by 21 sheet, are caused to travel about a square, each plate in turn being inked, wiped, fed with a sheet, printed, and the sheet removed. The speed is from 900 to 1400 sheets per hour. A five-h. p. compound d-c. motor is used, with 50 per cent field control. The motor speed may be 500/750 or 875/1325 according to the make of press. A predetermined speed or full-automatic controller is employed. Dynamic brake, giving a very quick stop, is essential. Both gear and belt drive have been used.

A rotary plate press is used for postage stamps. It is fed from a roll and prints the stamps on a continuous web, which is afterwards gummed and perforated. Rotary engraving presses are also used for bonds, stock certificates, etc., and could undoubtedly be used for paper currency, although practise has confined this work to the slower flat-plate machines.

The rotary presses used for engraving work have been usually built to order, and there is no general standard. Most of those constructed will come within a range requiring, for the smallest 3 h. p., and for the largest 10 h. p. The motors should have from 50 to 75 per cent field control, be compound-wound, non-reversible, with predetermined speed or full-automatic control, and dynamic brake. Gear drive is employed.

Die Presses. These presses are so called because the plates from which the impression is made is usually called a die. Commercial die presses are built in sizes ranging from a 2 in. by 4 in. card to a 6 in. by 10 in. card, requiring from ¾ to 3 h. p., depending on the size of the machine. Die presses operate on either the crank (or eccentric) action or the toggle action to give the necessary pressure to force the paper or card a little into the depressions in the plate. A clutch is employed for throwing in the action of the machine.

It is customary with die presses to employ compound-wound d-c. motors with 50 per cent field control and 40 per cent armature control, using predetermined speed type self-starting controllers. On alternating

current, two or three-phase varying-speed wound rotor motors are successfully employed.

It may be here stated that, while no mention of alternating-current motors was made in connection with rotary and flat-bed steel-plate presses, this is simply because the engraving business is a close industry and the few large plants use d-c. motors entirely. There is nothing in the engraving press which makes its operation by varying-speed wound rotor polyphase motors any more of a problem than that involved in operating type presses; and type presses of all kinds are very successfully operated in great numbers with a-c. motors.

ROTOGRAVURE

The rotogravure process was developed in Germany, and the first rotogravure presses used in the United States were built there. The process is a development of the photogravure process, a process in which a design was photographed on copper plate and the lines necessary to reproduce the picture etched below the surface so as to receive the printing ink as in direct hand engraving. It is the opposite of the half-tone process, in which the inked portions are raised above the surface. It is intaglio, and not cameo, printing; and, in fact, the presses are sometimes called intaglio presses. The process was the result of efforts to put photogravure on curved plates or cylinders and to run them at high speed with a continuous roll or webb, as in a newspaper press.

A rotogravure press is very like a rotary web magazine or newspaper press in general appearance. It ordinarily has one deck, feeds from one roll of paper, prints on both sides at one passage of the web, using two printing cylinders. The speed is low compared to newspaper printing (stereotype), or about the same as high-grade magazine work—about 4000 an hour, but work has been done at a rate as high as 10,000 cylinder revolutions per hour. One factor limiting the speed is the time to dry the ink between impressions. The ink is quite different from ordinary printing ink. It has a petroleum base and it is quite volatile. Special drying apparatus is required.

The printing is done from continuous copper-sheathed steel cylinders instead of plates, the cylinder with its shaft or arbor being substantially one solid mass. It is prepared by copper-plating the steel core. After use the cylinder is turned down to a new surface. Eventually it must be replated. Formerly the copper cylinders were cast hollow, turned up inside, and forced over the arbor by hydraulic pressure. The present system takes much less work.

In the process, the copy is prepared first—photographs, drawings, type matter, etc. The copy is then photographed to the proper size on a glass or a film, making a negative. A print is made from the negative on a sensitized carbon paper that has been screened, giving the proper cross-lines. This carbon paper print, having been developed, is laid against the copper cylinder, registered as to position, and rolled up to give close contact. Hot water is then applied to soften the paper, which is then offset, leaving an impression on the cylinder. This impression is then etched in with acid to the desired depth. The film is then washed off with turpentine or similar reagent, leaving a perfectly engraved surface ready for printing.

In the press the copper cylinder is in direct contact with the ink at one segment of its circumference. A soft metal knife, oscillating back and forth, clears off all the ink except that which remains in the engraved or subsurface lines.

Rotogravure presses, in common with other rotary web presses, require a specialized form of motor drive. The cylinders must be revolved at a steady, low speed of 8 to 10 rev. per min. for threading in the paper. They must then be accelerated smoothly and evenly to 80 or 100, or even to 165 rev. per min. for printing. The speeds must be capable of variation through a considerable range, so as to get the maximum speed which any given stock of paper, under any of widely different conditions, may admit. The torque increases somewhat more rapidly than increase in speed, the load consisting of gear and bearing friction, cylinder pressure, paper tension, action of the folder (if used), and the resistance due to the viscosity of the ink.

Automatic push-button control is generally employed. Quick stop is important, and a device for stopping in case the web breaks is desirable. Rotogravure presses have been constructed taking as little as 5 h. p., and others taking as much as 40 h. p. On the larger presses a two-motor drive is used, consisting of one main driving motor for running the press on speed and one starting motor, one-fifth or one-eighth the size of the larger motor, for starting and threading. The starting motor is connected to the press through slow-motion gearing, and with an automatic over-running, throw-off clutch which disengages the starting motor when the press shaft is driven above the starting speed by the large motor. The smaller presses may, when direct current is available, be operated successfully by a single motor, using a speed range of 3:1 by field control and a low speed by armature resistance of one-fifth of normal. On alternating current, however, the two-motor drive is recommended, down as small as 7½ h. p.

MOTOR FOR SUBSIDIARY PROCESS—ROTOGRAVURE

Copper Plating. The steel printing cylinders are covered with a copper sheath about ¼ to ⅜ in. thick in an electroplating bath, the standard copper-plating process being used. Six volts is ordinarily employed, the current varying from 1200 to 2500 amperes according to the amount of work to be done, number of tanks, etc. The plating generator is usually direct-coupled to a constant-speed motor.

As in the electrotyping processes, water and air

pumps are required to keep up the water supply in the tanks and to agitate the electrolyte. The former may be, the latter always, is required. Manufacturers of electroplating supplies list water pumps of from 10 to 100 gallons per minute capacity and taking from $\frac{1}{4}$ to 5 h. p. Positive-pressure air pumps, for keeping the bath in constant commotion, are listed in capacities of from 20 to 300 cu. ft. per min. and requiring from $\frac{1}{4}$ to 10 h. p. Speed variation of $1\frac{1}{2}$:1 or 2:1 is desirable, to regulate the volume. The pressure will vary from one to five lbs. per sq. inch.

When the cylinder has been built up to the required thickness of copper, it is turned down true in a special lathe, and the same tool is used to take off the etching after a run is completed, to prepare the cylinder for new work. This process is repeated till the cylinder is too thin, and then it is built up again in the copper bath.

The lathe is driven by adjustable speed motor of approximately three h. p., for a lathe taking a 70 in. cylinder; 3:1 speed control is desired. The cuts taken are light and the work done is relatively small and the friction load relatively large, the lathe being of heavy construction because of the weight and length of the cylinders.

On the rotogravure press itself, the adjustment of the bearings is essential because of changing diameter of cylinders with the turning down of the copper sheath. This adjustment is accomplished in some makes by motor driven screws, one under each bearing, and geared together. A small series-wound motor, about $\frac{1}{2}$ h. p., is employed for this service.

Drying of the ink is, as mentioned above, of prime importance. Electric heat has been successfully applied for this purpose. The web is passed in front of a large flat heating element, which may consume as much as 10 kw.

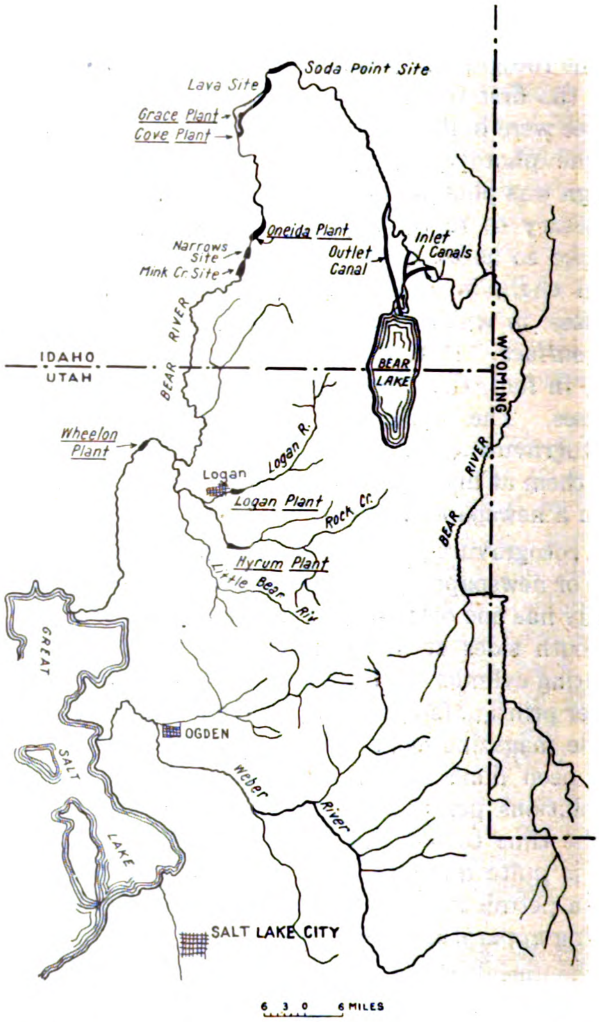
HYDROELECTRIC ADDITIONS TO THE UTAH POWER AND LIGHT COMPANY

Unusual interest attaches to the plans of the Utah Power and Light Company, under preliminary permit issued by the Federal Power Commission last July, for extensive power developments on Bear River in southeastern Idaho.

The completed project will add 21,500 horse power of hydroelectric energy to the generating capacity of the company's system, now capable of developing about 165,000 of hydroelectric horse power, and will be connected with the big main transmission system operating at 130,000 volts, extending from Grace plant, in Idaho, to Salt Lake City, a distance of 134 miles, and supplying a population of 300,000 with power, much of which is used in mining and manufacturing.

Bear Lake, 135 square miles in area, lies in a basin tributary to the river near the Idaho-Utah line. The Utah Power & Light Company now diverts the flood waters of the river into the lake and at seasons of low water draws them back into the river. By release of this stored water the amount of power available is increased, and a great improvement in irrigation is effected.

At Soda Point, about 36 miles below Bear Lake Reservoir, the river enters a canyon and descends swiftly to Logan Valley. In this stretch the company now has three hydroelectric plants, with a combined capacity of 94,300 horse power. Farther down, at



Utah Power and Light Company's New Developments on Bear River

Wheelon below Logan Valley, a fourth plant is located which can develop 9550 horse power.

Developments under the Commission's permit will be confined to four locations above Logan Valley. The two upper sites will have effective heads of 75 and 85 feet and each will have a primary capacity of about 6500 horse power. The two lower sites will be located immediately below the existing Oneida plant, and will develop about 9800 horse power.

Shunting Characteristics of the Relay in an A-C. Track Circuit Employed in Railroad Signaling

BY C. F. ESTWICK

Engineering Department, General Railway Signal Company

It is usually the practise in railroad signaling to automatically control the operation of signals and other safety devices in the system by means of a relay operated in an electrical circuit which is completed through the rails of the track. The track is sectionalized by placing insulated joints in the rails so that each section becomes insulated from adjoining sections. The rails are utilized throughout the entire length of a section as conductors for carrying current from a source of energy located at one end of the section to the track relay at the opposite end. The relay operates in a closed circuit and is normally energized. When a train enters a track section the wheels and axles of the cars form a conducting path for the current to flow directly from one rail to the other instead of flowing through the relay. This shunts the relay sufficiently to cause it to release its contacts thus allowing the signals to operate in such manner as to indicate the presence of the train. If the relay fails to shunt with a train in the section the signals not only fail to protect the train, but give false indications advising approaching trains that the track is clear. Continuous track circuits as they are employed in the present state of the art are recognized as the safest means of controlling signals, but even so where they are used the integrity of the entire signaling system is dependent upon the proper functioning of the track relay. It is therefore important to study the various characteristics of the track circuit particularly in connection with the shunting action of the relay.

Much consideration has been given to the question of shunting, more especially where the track circuits are operated with continuous current, and a great deal that has been developed in connection with continuous-current circuits applies to the alternating-current track circuit. There are also conditions that exist in a-c. track circuits that are due to the use of alternating current and to the characteristics of the different types of a-c. relays employed. The track relays that are mostly used in a-c. signaling are "two-phase" relays which have one phase, or group of windings, connected to the track and the other phase supplied with energy from a separate transformer. It is the intention in this discussion to consider the induction motor type relay which consists of a contact mechanism operated from the shaft of a motor of special design. The motor has a nonmagnetic rotor acted upon by a stator which is wound similarly to that of an ordinary two-phase induction motor. The two sets of windings of the stator are connected to separate terminal posts, one set constituting the track phase and the other the local phase. The track phase is wound to a low impedance which depends upon the conditions of the track circuit, whereas the local phase is wound to a higher impedance which is determined by the power required in the windings and the voltage available at the transformer.

The characteristics of the relay are as follows:

(1) If the local phase is constantly energized and the phase displacement between the current in the track and local phase windings is constant the torque developed at the rotor shaft varies directly as the current in the track phase.

(2) If the current in both the track and local phase windings are constant and the phase displacement is varied the torque will vary directly as the sine of the angles of displacement. When the phase displacement is 90 deg. the torque is a maximum, and when it is 0 deg. or 180 deg. the torque is zero.

(3) When the current in the track phase leads the current in the local the torque tends to operate the relays in one direction, and when it lags behind the local current the tendency is to operate in the opposite direction.

In making laboratory or shop tests on a relay, means are generally available for varying both the size of the currents in the windings and their phase displacement. It is usual to make shop tests at 90 deg. phase displacement and describe the operating characteristics of the relay accordingly.

In operation in a track circuit the phase displacement of the currents in the windings may be poor, in some cases probably less than 20 deg., whereas in other cases it may approximate 90 deg. or it may be more than 90 deg. This depends upon the length of the track section, the impedances in the circuit and the resistance of the ties and the ballast. In the same track circuit the current in the track phase of the relay and the phase displacement are found to vary on account of changeable weather conditions which cause a considerable variation in the ballast resistance. When a train enters a track circuit the application of the shunt across the rails decreases the current in the relay and causes a change in the phase displacement. If the effect is such as to increase the phase displacement the current will have to decrease more than would otherwise be necessary to cause the relay to release its contacts, but on the other hand if the phase displacement becomes less the relay will release its contacts with a smaller decrease in current. It is therefore necessary to consider vector values of the currents in order to understand the effect of a shunt on the operation of the relay.

Where there is a switch in a main track that leads

to a branch track or at a cross-over it is practise to install a switch circuit controller which is operated mechanically by the throwing of the switch. The circuit controller is provided with contact fingers that are wired to the rails and are operated in such manner that when the switch is open the rails become short-circuited. The shunt through the contact fingers is usually of a much higher resistance than that obtained through the wheels and axles of a car or locomotive. At switch locations the rails on the main track are bonded to those of the turn out in such manner as to carry the track circuit out at least as far as the fouling point. It sometimes happens that the rails leading to a siding that is not much used become rusted to such an extent that very poor contact is made between the rails and the wheels of a car standing on the track. It is evident that a relay is expected to release its contacts when the shunt across the rails is of a comparatively high resistance. The relay that affords

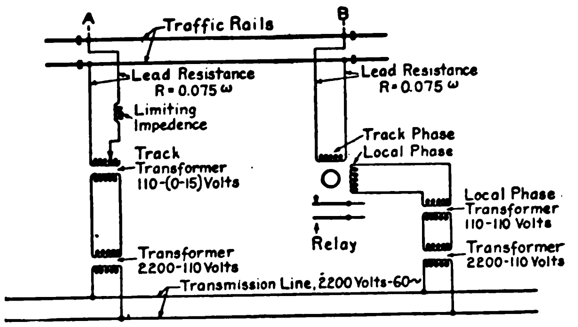


Fig. 1—Typical A-C. Steam Road Track Circuit

the greatest factor of safety in operation is that which will shunt with the highest resistance connected across the rails. The quality of the shunting in a track circuit is measured by the maximum shunting resisttance that will cause the contacts of the relay to open. The effect on the relay, of course, varies with the position on the track at which the shunt is applied. In some track circuits the relay will shunt better when the shunt is applied at one end of the track and in others when the shunt is applied at the opposite end. In considering the shunting characteristics of a track circuit the maximum shunting resistance should be determined for shunting at both ends of the track.

The circuit diagram shown in Fig. 1 is a typical steam road track circuit supplied with alternating current at 60 cycles over a high-voltage transmission line. The transformer that supplies energy to the track is provided with taps on the secondary winding arranged so that the voltage can be adjusted in steps of 1 volt up to 15 volts. The relay shown is of the type already described and has the local phase supplied with energy at 110 volts.

The characteristics of the windings are as follows:

Local phase: 110 volts, 0.252 ampere, 18 watts.
27.7 volt-amperes, 437 ohms impedance
0.65 power factor.

If Z_{L0} represents the impedance and I_{L0} the current in the local phase with reference to the voltage at the transformer these values may be written:

$$Z_{L0} = 437 \angle 49^\circ.5 \text{ ohms}$$

and

$$I_{L0} = 0.252 \nwarrow 49^\circ.5 \text{ ampere}$$

Track phase: 0.64 ohm impedance
0.602 power factor

This impedance may be represented by Z_R and expressed:

$$Z_R = 0.64 \angle 53^\circ \text{ ohm}$$

The operating characteristics of the relay when tested at 90 deg. phase displacement with the local phase constantly energized are:

Current that causes the relay to pick up to just close its front contacts, $i_c = 0.19$ ampere.

Current that will pick up the relay to its front stop $i_m = 0.22$ ampere.

Current that allows the relay to release its contacts $i_d = 0.115$ ampere.

The above current values and all currents and voltages referred to hereafter will be understood to be effective or r. m. s. values.

The limiting impedance Z_l connected in the circuit between the transformer and the rails is adjusted to 3 ohms with a power factor 0.174, *i. e.*

$$Z_l = 3 \angle 80^\circ \text{ ohms}$$

The leads connecting the relay to the track and those between the transformer and track have a resistance $R = 0.075$ ohm.

The impedance of the receiver Z_B equals the impedance of the relay and leads to the track, and the impedance of the total limiting impedance Z_L includes the resistance of the lead, thus

$$Z_B = Z_R + R = 0.68775 \angle 48^\circ.004 \text{ ohm}$$

and

$$Z_L = Z_l + R = 3.0139 \angle 78^\circ.596 \text{ ohms}$$

The voltage at the track transformer is adjusted to 7 volts.

Properties of the track: Length of section $L = 9000$ feet.

The rails are 90 lb. per yd., A. S. C. E. section bonded with 2 No. 6 A. W. G. copper-clad bond wires at each joint. The impedance of the rails is 0.3 ohm per 1000 ft. and the power factor 0.866. The ballast is stone and is about 50 per cent clear of the base of the rails. The resistance of the ballast varies from 5 ohms to 20 ohms per 1000 ft. depending upon weather conditions.

The impedance of the rails and leakage conductance during rainy weather conditions are:

$z = 0.3 \angle 30^\circ$ ohm, loop impedance of the rails per 1000 ft.

$g = 0.2$ mho, conductance of the ties and ballast per 1000 ft.

In the present instance the rail impedance and ballast conductance are assumed to be evenly distributed along the track.

The attenuation constant α and the surge impedance of the track z_0 may be determined from the formulas:

$$\alpha = \sqrt{z\,g} \quad \text{and} \quad z_0 = \sqrt{z/g}$$

whence $\alpha = 0.24495 \angle 15° = 0.23660 + j\,0.06340$ hyp

and $z_0 = 1.2247 \angle 15°$ ohms

The hyperbolic angle that corresponds to any length of track varies directly as the length. The angle α corresponds to unit length of track, therefore the angle θ which corresponds to the length of track L, from A to B, equals $L\,\alpha$ or

$$\theta = 9\,\alpha = 2.1294 + j\,1.0647 \text{ hyps.}$$

Most of the problems that arise in connection with the track circuit can be most easily solved by the method of first determining the position angles at different positions on the track and then expressing the relations between the currents, voltages and impedances in the circuit in terms including the surge impedance and functions of the position angles. In studying the conditions at the relay and transformer ends of the circuit it is only necessary to determine the position angles δ_A and δ_B for the positions A and B at the ends of the track section. These position angles are determined from the equations:

$$\delta_B = \tanh^{-1} Z_B / Z_0 \quad \text{and} \quad \delta_A = \delta_B + \theta$$

The position angles and the following functions have been computed from the above relations by employing well-known formulas:

$$\delta_B = 0.44976 + j\,0.36460 \qquad \delta_A = 2.5792 + j\,0.93518$$

$$\sinh \delta_B = 0.58604 \angle 42°.147 \qquad \sinh \delta_A = 6.6045 \angle 53°.896$$

$$\cosh \delta_B = 1.0436 \angle 9°.143 \qquad \cosh \delta_A = 6.5821 \angle 53°.266$$

$$\tanh \delta_B = 0.56155 \angle 33°.004 \qquad \tanh \delta_A = 1.0034 \angle 0°.630$$

The currents and voltages in the circuit may be expressed as complex quantities or described graphically as "plane vectors." If the voltages at the secondaries of the transformers supplying current to the track circuit and to the local phase of the relay are assumed to be in phase these voltages may be selected as the standard phase and described as having a slope $\angle 0°$. All other currents and voltages will then be expressed to show their phase with reference to the voltages at the transformers. The voltage E at the secondary of the track transformer may therefore be written:

$$E = 7 \angle 0° \text{ volts}$$

If a shunt having a variable conductance G_S is connected across the rails of the track the relation between G_S and the current I_S in the track phase of the relay may be expressed by the equation:

$$G_S = \frac{E\,Y}{I_S} - K$$

This equation applies generally to the steam-road track circuit or to the electric-road track circuit where impedance bonds are employed to provide for the return of the propulsion current. It also applies whether the shunt is connected at either end of the track or at some intermediate position. The first term of the second member represents the admittance of the entire circuit between opposite points on the track where the shunt is applied, and the second term represents the same admittance less the conductance of the shunt.

When the shunt is applied at the A end of the track the values of Y and K are expressed in the following equations:

$$Y = \frac{\cosh \delta_B}{Z_l\,Z_0 \sinh \delta_A}$$

$$\text{and} \quad K = \frac{Z_l - Z_0 \tanh \delta_A}{Z_l\,Z_0 \tanh \delta_A}$$

The values of Y and K have been computed from these equations and are as follows:

$$Y = 0.042808 \angle\!\!\!\!\smallsetminus 138°.349$$

and $K = 0.84924 - j\,0.54447 = 1.0088 \angle\!\!\!\!\smallsetminus 32°.665$

Before proceeding with the question of the shunting it may be well to consider the conditions in the circuit before the shunt is applied, that is, when the section is unoccupied by a train. In this case $G_S = 0$ in the above equation. If the current in the track phase of the relay is represented in this case by I_B the equation becomes

$$I_B = \frac{E\,Y}{K}$$

The value of the current as obtained from this equation is:

$$I_B = 0.29703 \angle\!\!\!\!\smallsetminus 105°.684 \text{ ampere}$$

If γ represents the slope of the current in the track phase, β the slope of the local phase current and ϕ the phase displacement,

$$\phi = \beta - \gamma = \angle\!\!\!\!\smallsetminus 49°.5 - \angle\!\!\!\!\smallsetminus 105°.684 = +56°.184$$

The current i at 90 deg. phase displacement that gives operation of the relay equivalent to that obtained when I_B is flowing in the track phase equals the size of I_B, represented by $|I_B|$, multiplied by the sin ϕ, that is:

$$i = |I_B| \sin \phi = 0.24678 \text{ ampere}$$

The ratio $i / i_m = 1.122$ indicates that the adjustment of the track circuit gives satisfactory operation of the relay and provides a margin over the minimum working current i_m of about 12 per cent to allow for variations in the transmission line voltage.

The most important problem that arises in connection with the shunting of the relay is to determine the maximum shunting resistance or the minimum value of G_S which will shunt the relay so that the front contacts open. To determine the minimum value of G_S the general equation given above may be written in the form:

$$K + G_S = \frac{E\,Y}{I_S}$$

This equation may be readily solved graphically by a

construction as shown in Fig. 2. In laying out the diagram the dot and dash line $o\,L$ is first drawn at an angle $\overline{\angle}\ 49°.5$ to represent the slope of the current in the local phase. The line $o\,c$ is drawn at 90 deg. to the line $o\,L$. Then on $o\,c$ lay off $o\,d$ to a convenient scale, to represent the current $i_d = 0.115$ ampere at 90 deg. phase displacement. The line $a\,b$ is then drawn through d parallel to $o\,L$. It will be seen that any vector drawn from the origin and terminated in the line $a\,b$ has a component $o\,d$ displaced 90 deg. from the local current. All such vectors represent current values that give operation of the relay equivalent to that obtained by $o\,d$. Since all possible vector values of the current that just allow the relay to release its contacts terminate in $a\,b$ it may be said, in this sense, that $a\,b$ represents the drop-away current and this includes the current I_s. The line $a\,b$ is then inverted by drawing the circle S_1 to pass through the origin, so that its diameter lies on the line $o\,c$. The length

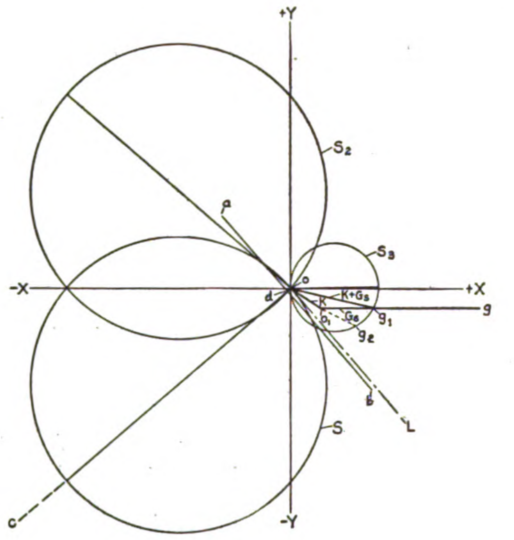

FIG. 2

of the diameter is made numerically equal to the reciprocal of i_d. The vector value of the diameter of the circle may be expressed:

Diameter $S_1 = 1/i_d \angle\ (\beta - 90°) = 8.6957\ \overline{\angle}\ 139°.5$.

The circle S_2 is drawn as the reflection of circle S_1 with relation to the horizontal axis. The vector value of the diameter of S_2 is the same as the diameter of S_1 except that the sign of the slope is changed, thus:

Diameter $S_2 = 1/i_d \angle\ (-\ \beta + 90°)$

$$= 8.6957 \angle\ 139°.5$$

The circle S_2 is the reciprocal of the line $a\,b$. Any vector from the origin that terminates in the circumference is the reciprocal of a corresponding vector drawn from the origin and terminated in $a\,b$. Circle S_2 therefore includes the value $1/I_s$. Then operating upon the circle S_2 by $E\,Y$ in such manner as to vary its size by a factor equivalent to the size of $E\,Y$ and to rotate it through an angle equal to the slope of $E\,Y$ gives the circle S_3 which represents vector values that include $\dfrac{E\,Y}{I_s}$. The diameter of circle S_3 may be expressed:

$$\text{Diameter } S_3 = \frac{E\,Y}{i_d} \angle\ (-\ \beta + 90°)$$

$$= 2.6057 \angle\ 1°.151$$

The line $o\,o_1$ is drawn to the same scale in mhos to represent the vector value of $K = 1.0088\ \overline{\angle}\ 32°.665$ A line $o_1\,g$ of indefinite length is drawn horizontally to the right from o_1, the terminus of vector K. Since the slope of conductance is assumed to be $\angle\ 0°$ this line may be taken to represent all possible values of G_s. It will be seen that any value of $K + G_s$ may be described by a vector drawn from the origin to terminate in the line $o_1\,g$, but $K + G_s = \dfrac{E\,Y}{I_s}$ therefore, the particular value of $K + G_s$ which fulfills the conditions of both members of the equation is represented by a line $o\,g_1$, drawn to the intersection of the circle S_3 with the line $o_1\,g$. By scaling the line $o_1\,g_1$ the minimum value of the conductance is found to be:

$$G_s = 1.6245$$
$$\text{or} \quad R_s = 0.61556$$

Instead of solving the problem to determine the minimum value of G_s by the graphical method the problem may be solved more accurately by employing algebraic formulas that are derived from a solution of the equation $G_s = \dfrac{E\,Y}{I_s} - K$. This solution of the equation is given as follows:

Let $I_s = \dfrac{i_d\,\epsilon^{j\gamma_s}}{\sin\phi_s}$ and let $Y = y \angle v = y\,\epsilon^{jv}$

in which $\phi_s = \beta - \gamma_s$; y represents the size of Y and ν the slope of Y.

Then by substituting these values in the general quation this may be written:

$$G_s = \sin\phi_s \,.\, \frac{E\,y}{i_d} \,.\, \epsilon^{j(v - \gamma_s)} - K$$

Multiplying and dividing the first term of the second member of the equation by $\epsilon^{-j\beta}$, the equation becomes:

$$G_s = \sin\phi_s \,.\, \frac{E\,y}{i_d} \,.\, \epsilon^{j\phi_s} \,.\, \epsilon^{j(v-\beta)} - K$$

Let $\dfrac{E\,y}{i_d} \,.\, \epsilon^{j(v-\beta)} = m + j\,n$ and $-\,K = e + j\,f$

then $G_s = \sin\phi_s \,.\, \epsilon^{j\phi_s}\,(m + j\,n) + e + j\,f$

Remembering that $\epsilon^{j\phi_s} = \cos\phi_s + j\sin\phi_s$ the latter equation becomes:

$$G_s = \sin\phi_s\,(\cos\phi_s + j\sin\phi_s)\,(m + j\,n) + e + j\,f$$

The equation is now cleared of expotential values and may be expanded and then by equating real components to G_s and imaginary components to zero the following simultaneous equations are obtained:

$$G_s = \sin\phi_s\,(\,m\cos\phi_s - n\sin\phi_s\,) + e$$
$$o \;=\sin\phi_s\,(\,n\cos\phi_s + m\sin\phi_s\,) + f$$

By solving these equations the following formulas have been derived for the purpose of determining the values of G_s and ϕ_s:

$$G_s = e - n\,/\,2 \pm \sqrt{(\,n\,/\,2\,)^2 - m\,f - f^2}$$

$$\sin^2\phi_s = \frac{-\,n\;\,G_s - e) - m\,f}{m^2 + n^2}$$

The sign be'ore the radical in the first of these equations is taken so that G_s is positive. If the value of $\beta - \gamma_s$ is negative, as is the case when the track phase current leads the local current, the last equation containing the expotential $\epsilon^{j\phi_s}$ becomes:

$$G_s = \sin\phi_s\,.\;\epsilon^{-j\phi_s}\;(m + j\,n) + e + j\,f$$

By substituting $\cos\phi_s - j\sin\phi_s$ for $\epsilon^{-j\phi_s}$ and proceeding the same manner as above the final formulas become:

$$G_s = e + n\,/\,2 \pm \sqrt{(n\,/\,2)^2 + m\,f - f^2}$$

$$\sin^2\phi_s = \frac{n\,(G_s - e) + m\,f}{m^2 + n^2}$$

These equations offer a simple algebraic solution of the general equation and may be employed as follows in working out numerical values.

The values of m and n are obtained from the equation

$$\frac{E\,y}{i_d}\,.\;\epsilon^{j\,(v-\beta)} = \frac{E\,y}{i_d}\,\angle\,(v - \beta)$$

$$= 2.6057 \nwarrow 88°.849 = 0.05234 - j\,2.6051$$

whence $m = +\,0.05234$ and $n = -\,2.6051$

The values of e and f are obtained from:

$$-\,K = -\,(1.0088 \nwarrow 32°.665) = -\,0.84924 + j\,0.54447$$

then $e = -0.84924$ and $f = +\,0.54447$

From the equation

$$G_s = e - n\,/\,2 \pm \sqrt{(n\,/\,2)^2 - m\,f - f^2}$$

the value of the conductance G_s is found to be:

$$G_s = 1.6245 \text{ mhos}$$

or

$$R_s = 0.61556 \text{ ohm}$$

The angle ϕ_s as obtained from the formula

$$\sin^2\phi_s = \frac{-\,n\,(G_s - e) - mf}{m^2 + n^2}$$

is found to be:

$$\phi_s = +\,76°.436$$

The slope of the current in the track phase of the relay $\gamma_s = \beta - \phi_s = \nwarrow 125°.936$ and the size of the current equals $\dfrac{i_d}{\sin\phi_s} = 0.11830$ ampere.

The value of the current in the track phase may then be expressed in the polar form thus:

$$I_s = 0.11830 \nwarrow 125.°936 \text{ ampere.}$$

In solving the general equation it has been assumed that the shunt is applied at the A end of the track. The problem will now be considered with the shunt connected at the B end. The diagram in Fig. 3 shows the normal arrangement of the track circuit with the shunt connected at B and that in Fig. 4 shows the same track circuit and arrangement of conductors except that the track transformer has been transposed from the point T to the point R. From a general principle that applies to electric circuits it will be

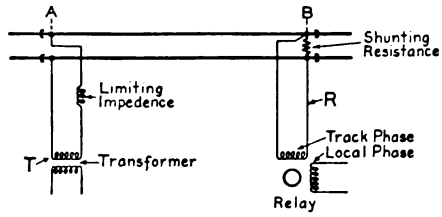

Fig. 3—Normal Arrangement of Track Circuit with Shunting Resistance Connected at B

understood that, with the same voltage at the transformer in both circuits, the current, considered as a complex quantity, in the track phase of the relay in Fig. 3 is the same as the current in Fig. 4 that flows through the limiting impedance.

With the circuit as in Fig. 4 in mind the general equation for shunting may be written:

$$G_s' = \frac{E\,Y'}{I_s'} - K'$$

The position angles for the A and B ends of the track for the circuit in Fig. 4 are determined from the equations:

$$\delta_A' = \tanh^{-1} Z_L\,/\,Z_0 \quad\text{and}\quad \delta_B' = \delta_A' + \theta$$

The position angles and the sinh, cosh and tanh of the angles have been computed and are as follows:

$$\delta_A' = 0.16038 + j\,1.2123$$
$$\delta_B' = 2.2898 + j\,1.7828$$
$$\sinh\delta_A' = 0.95016 \angle 86°.590$$

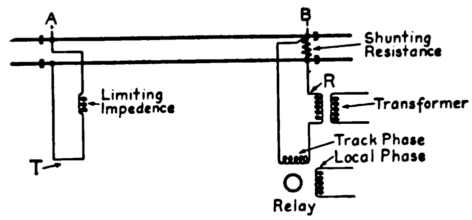

Fig. 4—Same Network of Conductors as Shown in Fig. 3 with Transformer Transposed from T to R

$$\sinh\delta_B' = 4.9828 \angle 101°.909$$
$$\cosh\delta_A' = 0.38610 \angle 22°.994$$
$$\cosh\delta_B' = 4.8904 \angle 102°.393$$
$$\tanh\delta_A' = 2.4609 \angle 63°.596$$
$$\tanh\delta_B' = 1.0189 \nwarrow 0°.484$$

The values of Y' and K' may now be expressed:

$$Y' = \frac{\cosh\delta_A'}{Z_B\,Z_0\sinh\delta_B'}$$

and

$$K' = \frac{Z_B + Z_0\tanh\delta_B'}{Z_B\,Z_0\tanh\delta_B'}$$

The value of K' may also be obtained from the relation:

$$K' = \frac{Y' K}{Y}$$

The values of Y' and K' as computed from these equations may be given as follows:

$$Y' = 0.09199 \;\overline{\diagdown}\; 141°.918$$
$$K' = 2.1680 \;\overline{\diagdown}\; 36°.235$$

The algebraic solution to determine G_s', I_s', the current in the track phase of the relay in Fig. 3, and ϕ_s' is the same as in the case where the shunt is connected to the rails at A, thus:

$$\frac{E\,y'}{i_d} \angle (\nu' - \beta) = 5.5996 \;\overline{\diagdown}\; 92°.419$$
$$= -0.23634 - j\,5.5946$$

whence, $m' = -0.23634$ and $n' = -5.5946$

$$-K' = -(2.1680 \;\overline{\diagdown}\; 36°.235) = -1.7486 + j\,1.2815$$

or $e' = -1.7486$ and $f' = 1.2815$

Then

$$G_s' = e' - n'/2 \pm \sqrt{(n'/2)^2 - m' f' - f'^2}$$

or $= 3.5953$

$$R_s' = 0.27814$$

$$\sin^2 \phi_s' = \frac{-n'(G_s' - e') - m' f'}{m'^2 + n'^2} = 0.96316$$

or $\sin \phi_s' = 0.98141$

and $\phi_s' = +78°.934$

Then $\gamma_s' = \beta - \phi_s' = \;\overline{\diagdown}\; 128°.434$

The size of the current I_s' equals

$$\frac{i_d}{\sin \phi_s'} = 0.11718 \text{ ampere}$$

The current I_s' in the track phase of the relay may then be written:

$$I_s' = 0.11718 \;\overline{\diagdown}\; 128°.434 \text{ ampere}$$

In what has been said previously in regard to the current in the relay it has been assumed that the maximum shunting resistance is connected across the track, and although this is important, it is also advisable to investigate the conditions when the shunting resistance is something other than the maximum resistance, as these are conditions that occur in practise.

The current in the track phase of the relay, when a variable conductance is applied as a shunt at A, may be expressed by the general equation in the form:

$$I_s = \frac{E\,Y}{K + G_s}$$

This equation may be readily solved graphically by a construction as shown in Fig. 5 in which the vector $K = 1.0088 \;\overline{\diagdown}\; 32°.665$ is first drawn to scale from the origin with reference to the rectangular coordinates. A line $o_1\,g$ of indefinite length is drawn horizontally to the right from o_1 to represent the conductance G_s. Any value of $K + G_s$ when G_s is variable, may be represented by a vector drawn from the origin so as to terminate in $o_1\,g$. With this thought in mind the line $o_1\,g$ may be taken to represent the admittance $K + G_s$. The line $o_1\,g$ is then drawn indefinitely to the left and is found to intersect o-Y at a point h. The circle S_4 which passes through the origin is drawn so that its diameter coincides with the negative ordinate o-Y and numerically equals the reciprocal of the distance $o\,h$. The circle S_5 is then drawn as the reflection of circle S_4 with reference to the horizontal axis. Circle S_5 represents all vector values of $\dfrac{1}{K + G_s}$. Since conductance has been assumed to be positive the negative values of G_s cannot exist physically. When G_s is confined to positive values the impedances represented by $\dfrac{1}{K + G_s}$ are vectors from the origin that

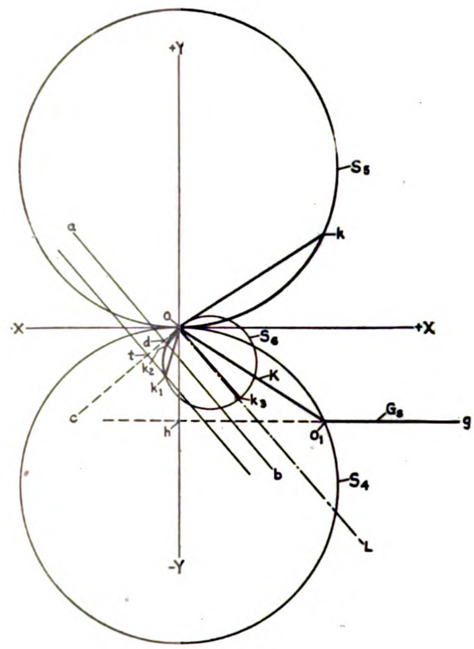

Fig. 5

terminate in the shorter arc of the circle S_5 between o and k. When G_s is zero the impedance $1/K$ is represented by vector $o\,k$ and as G_s increases to infinity the vector representing $\dfrac{1}{K + G_s}$ varies so that its terminus passes over the arc from k to o.

Operating on the circle S_5 by

$$E\,Y = 0.29965 \;\overline{\diagdown}\; 138°.349$$

changes the diameter in size by the factor 0.29965 and rotates the circle through an angle 138°.349 in a negative direction. This gives the circle S_6 which represents all vector values of $\dfrac{E\,Y}{K + G_s}$, but the only possible values of $I_s = \dfrac{E\,Y}{K + G_s}$ are those determined from G_s taken positively, and these are vectors that terminate in the shaded arc between k_1 and o. When $G_s = 0$ the vector $o\,k_1$ is the current in the track phase of the relay when the block is unoccupied. As the

conductance G_s is connected to the track and varied from zero to infinity the current I_s varies over the arc of the circle from k_1 to o. The angle between $o\,k_1$ and the diameter $o\,k_3$ of the circle S_6 is the same as the angle between vector K and the ordinate o-Y. Any other current value represented by a vector from o to the arc $o\,k_1$ is displaced from the diameter by the same angle that a corresponding vector from o to the line $o_1\,g$ is displaced from ordinate o-Y. The distance between o_1 and the terminus of this latter vector, $K + G_s$, represents the corresponding value of G_s.

For the purpose of comparing the phase displacement that exists between the currents in the track and local phase windings as G_s is varied the line $o\,L$ is drawn at $\angle\ \beta$ to indicate the slope of the local current. The angle between any value of I_s and the $o\,L$ indicates the phase displacement. The line $o\,c$ has been drawn at 90 deg. to $o\,L$ to show the current at 90 deg. phase displacement that will give equivalent operation of the relay by projecting any value of I_s on the line $o\,c$. The line $o\,d$ represents the drop-away current and the line $o\,t$ the current that gives normal operation of the relay. A circle S_6' might be drawn on the same diagram to show how the current in the relay varies when the shunt is connected to the rails at B. This circle is not shown because, in this particular case, the arcs of the two circles would nearly coincide.

In the practical adjustment of a track circuit it is usual to make the adjustment in wet weather when the ballast resistance is low; in any case, the adjustment must be such that there will always be sufficient voltage at the transformer to operate satisfactorily the relay. If as in the present case, the voltages is adjusted when the ballast resistance is low, then when the ballast dries out and the resistance increases there is an excessive current in the relay. The shunting then becomes poorer and the maximum shunting resistance is of course, less. In order to show the characteristics of the track circuit in regard to shunting under dry weather conditions, computations have been made on the assumption that the ballast resistance increases from 5 ohms to 20 ohms per 1000 ft. of track. The results of these computations are given in the table below, together with the numerical data obtained above, for comparison.

Data on Shunting or Relay in 9000-Ft. Track Circuit
$E = 7 \angle 0°$ Volts $Z_l = 3 \angle 80°$ Ohms $Z_R = 0.64 \angle 53°$ Ohm

Ballast Resistance	Track Section Unoccupied	Track Section Shunted at A	Track Section Shunted at B
5 ohms	$I_B = 0.29703 \overline{\backslash}\, 105°.684$	$I_s = 0.11830 \overline{\backslash}\, 125°.936$	$I'_s = 0.11718 \overline{\backslash}\, 128°.434$
•	$\phi = +56°.184$	$\phi_s = +76°.436$	$\phi'_s = +78'.934$
•	$\sin\phi = 0.83083$	$\sin\phi_s = 0.97211$	$\sin\phi'_s = 0.98141$
•	$i = 0.24678$	$G_s = 1.6245$	$G'_s = 3.5953$
•		$R_s = 0.61556$	$R'_s = 0.27814$
20 ohms	$I_B = 0.79965 \overline{\backslash}\, 74'.983$	$I_s = 0.12747 \overline{\backslash}\, 113'.948$	$I'_s = 0.13050 \overline{\backslash}\, 111°.288$
•	$\phi = +25°.483$	$\phi_s = +64°.448$	$\phi'_s = +61°.788$
•	$\sin\phi = 0.43024$	$\sin\phi_s = 0.90219$	$\sin\phi'_s = 0.88121$
•	$i = 0.34404$	$G_s = 3.8051$	$G'_s = 9.5770$
•		$R_s = 0.26281$	$R_s = 0.10442$

In referring to the table it will be seen that with the block unoccupied the current in the track phase increases in a ratio approximately 2.7:1 as between wet and dry weather conditions. This is not as bad as it would appear because the phase displacement becomes less. The equivalent current i at 90 deg. phase only increases in the ratio 1.4:1 as the ballast dries out. The application of a resistive shunt at the track increases the lag in phase of the current and gives a larger phase displacement. The phase displacement ϕ_s is not as unfavorable in dry weather as is evident by a comparison of the values of $\sin\phi_s$. It will be seen from the values of R_s that the shunting is not as good at the relay end of the track as it is at the transformer end.

Throughout the discussion it has been assumed that the shunting of the relay is accomplished by connecting a resistance across the track and this is the condition when the shunting is effected through contacts in a switch box, which is one of the most difficult conditions to meet. However, it has been claimed that the shunt through the wheels and axles of a train is somewhat inductive, but no reliable data appear to be obtainable as to the power factor of a train shunt. It can be shown in the present case that the relay will release its contacts more readily with an impedance shunt. For instance, in Fig. 2 the dotted line $o_1\,g_2$ which represents the admittance corresponding to a shunting impedance, is less than $o_1\,g_1$ the minimum conductance G_s. This is not always the case. It can be shown in a similar manner under some conditions that it becomes more difficult to shunt the relay with impedance than with resistance.

It may be well to refer to the importance of drawing the diagram in Fig. 5. In this case the current circle S_6 shows that the relay shunts as it is intended to do when a resistance is connected across the rails. There may be instances where the track circuit is poorly adjusted or where abnormal conditions arise such as high rail resistances due to broken bond wires, and when such conditions exist an excessive voltage may be applied to the track in an attempt to operate the relay. Under some of these unusual conditions when a fairly high resistance is connected across the rails the torque at the rotor shaft may increase instead of decreasing to allow the relay to release its contacts. Again, in three-position signaling when a shunt is connected it may happen that the relay instead of simply releasing its contacts will tend to pick up to close the contacts in a reverse direction. In investigating such conditions the current circle S_6 will be useful in determining the performance of the relay.

JOURNAL OF THE American Institute of Electrical Engineers

PUBLISHED MONTHLY BY THE A. I. E. E.
33 West 39th Street, New York
Under the Direction of the Publication Committee

WILLIAM MCCLELLAN, *President*

Subscription. $10.00 per year to United States, Mexico, Cuba, Porto Rico, Hawaii and the Philippines; $11.00 to Canada and $12.00 to all other countries. Single copies $1.00. Volumes begin with the January issue.

Changes of advertising copy should reach this office by the 15th of the month for the issue of the following month.

A. I. E. E. MIDWINTER CONVENTION
FEBRUARY 15-17, 1922

The 10th Midwinter Convention of the Institute will be held in New York, February 15-17, 1922, in the Engineering Societies Building. This will be the first meeting in 1922 under the new policy adopted by the Board of Directors which prescribes four general meetings of the Institute each year including the annual convention.

The Meetings and Papers Committee has in hand several papers which have been accepted, and is prepared to consider for this program any further manuscripts which may be received prior to December 15th. The complete program will be printed in the January JOURNAL.

NEW YORK SECTION MEETING CANCELLED

December 14 meeting. Because of a conflict of dates it has been necessary to cancel the joint meeting of the N. Y. Section of the Institute and the Metropolitan Section of the A. S. M. E. on "Central Station Operating" scheduled for December 14. It is also believed this cancellation will permit members to devote more time to the many outside affairs demanding attention at that season of the year.

FUTURE SECTION MEETINGS

Atlanta.—December 29, 1921. Subject: "Muscle Shoals" (illustrated). Speaker: Mr. C. G. Adsit, Chief Consulting Engineer. Georgia Railway & Power Co.

Baltimore.—December 8, 1921. Paper: "Design and Construction of the Westport Generating Station." Speaker: Mr. A. S. Loizeaux, E. E., Consolidated Gas & Electric Light & Power Co. Paper: "Operating Problems in the Westport Generating Station." Speaker: Mr. Abbott L. Penniman, Supt. of Steam Stations, Consolidated Gas, Electric Light & Power Co. The meeting will be held in the Service Building at the Westport Generating Station and will be followed by an inspection tr p through the station.

January 20, 1921. Paper: "The Use of Electricity for Industrial Heating." Speaker: Mr. C. F. Hirshfield, Chief of Research Department, Detroit Edison Company.

Connecticut.—December 15, 1921, Auditorium of Hartford Electric Light Company, 266 Pearl Street, Hartford. Subject: "Caribou Hydroelectric Development of the Great Western Power Company, California." Speaker: Mr. Albert A. Northrop, of the Stone & Webster Engineering Corporation, Boston.

Chicago.—December 16, 1921, Rooms of the Western Society of Engineers, 330 South Dearborn Street. Joint meeting with the Western Society of Engineers and the Association of Iron and Steel Electrical Engineers. Subject: "Application of Electric Power to Iron and Steel Industry." Speaker: W. S. Hall, E. E., South Works of the Illinois Steel Company.

Kansas City.—December 18, 1921. Telephone meeting.

Lehigh Valley.—January 12, 1921, at Bethlehem, Pa. Subject: "Electricity Aboard Ship."

Toronto.—December 9, 1921. Room 22, Chemistry and Mining Building, Toronto University. Subject: "Distribution Records and Overhead Distribution." Speaker: Mr. C. E. Schwenger, of the Toronto Hydroelectric System.

A. I. E. E. MEETING IN NEW YORK
NOVEMBER 17, 1921

The Joint Meeting of the Society of Naval Architects and Marine Engineers and the American Institute of Electrical Engineers was held at the Engineering Societies Building, on Thursday afternoon, Nov. 17, 1921. The meeting was called to order by President McClellan, of the Institute, who presided during the first half, and Admiral Capps of the Society of Naval Architects and Marine Engineers presided during the second half.

The following papers were presented:

"Electric Propulsion of Ships," by Mr. W. E. Thau, Member, A. I. E. E., Marine Engineer, Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa.

"Electric Auxiliaries on Merchant Ships," by Mr. E. D. Dickinson, Member, S. N. A. & M. E.; Associate, A. I. E. E., Mechanical Engineer, Marine Department, General Electric Co., Schenectady, N. Y.

These were discussed by W. L. R. Emmet, Charles F. Bailey, William Walker Smith, Capt. Q. B. Newman; Elmer A. Sperry; E. H. B. Anderson; Frederick C. Bates; G. H. Jett; G. A. Pierce; communicated discussion by Charles Rettie, of Liverpool, England; E. A. Stevens, Jr., W. McClelland, Director of Electrical Engineering, British Admiralty; Commander S. M. Robinson; H. L. Hibbard; Rear Admiral John K. Robison, Chief Engineer, U. S. Navy, followed by closure by the authors.

At the evening session an illustrated lecture on World Communication was given by Dr. Alfred N. Goldsmith, in which he traced the growth of the communication systems of the world by ocean cables, land lines and wireless. Moving pictures were shown of ocean cable laying, the operating machinery and apparatus of important stations and some of the largest and latest wireless equipments.

INSTITUTE PRIZES

At the meeting of the Board of Directors of the Institute of April 16, 1921, recommendations were approved establishing two Institute prizes to be awarded yearly to authors of worthy

papers. The following extracts from the report of the Committee on Coordination of Institute Activities embody the essential features of the procedure to be followed as outlined by them. Members of the Institute are reminded that January 15, 1921 is the last date for submitting to the Secretary papers that are to be considered in competition for the 1921 awards.

THE FIRST PAPER PRIZE

(1) This prize, established by the Board of Directors of the Institute, January 14, 1921, shall consist of $100 cash, and a suitable certificate, to be awarded each year to the author of the paper which is designated by a duly authorized committee of award as the most worthy original paper, presented during the year at a meeting of any Section of the Institute; by a member of the Institute who has never before presented a paper before the Institute or any of its Sections.

(2) To be considered for competition, the author, or an officer of the Section at which the author's paper was presented, shall submit the paper to the committee of award, by means of a written communication to the Secretary of the Institute, prior to January 15 of the year following the calendar year in which the paper was presented.

(3) Papers by joint authors are eligible for this competition, provided both authors meet the qualifications, in which case the prize shall be divided equally between the authors.

(4) The award shall be made by a committee consisting of the Chairman of the Meetings and Papers Committee as chairman, and the chairmen of the technical committes of the Institute, prior to June 1.

(5) The prize shall be presented at the Annual Convention of the Institute.

(6) The paper shall be published in the monthly JOURNAL or annual TRANSACTIONS of the Institute, or both.

(7) Manuscripts shall be submitted in duplicate and shall be typewritten on one side of paper of approximately 8½ by 11 inches. The letter entering the paper in the competition need not be accompanied by duplicate copies of the paper, provided suitable manuscript copies in duplicate have been submitted previously.

THE TRANSMISSION PRIZE

(1) This prize, established by the Board of Directors January 14, 1921, shall consist of $100, and a suitable certificate, to be awarded each year to the author of the paper which is designated by a duly authorized committee of award as the most worthy paper dealing with the art of transmitting electrical energy over considerable distances, presented during the year by a member of the Institute, at a meeting of the Institute or of any of its Sections.

(2) To be considered for competition, the author shall submit the paper to the committee of award, by means of a written communication to the Secretary of the Institute, prior to January 15 of the year following the calendar year in which the paper was presented.

Paragraphs three to seven as printed above under the heading "The First Paper Prize," also apply to this award.

A. I. E. E. TRANSACTIONS

An important change in the policy to be followed in the distribution of the annual TRANSACTIONS of the Institute has been adopted, as explained in a notice issued to all members of the Institute under date of November 12.

The volume covering the year 1920, publication of which has necessarily been delayed for financial reasons, is now completed and will be forwarded to all members entitled to receive a copy, during the month of December 1921.

The new policy takes effect with the volume covering the year 1921 in accordance with the following resolution which was considered and approved by the Board of Directors at a meeting in October 1920:

VOTED, that commencing with the volume of Institute TRANSACTIONS covering the year 1921, the practise of furnishing a copy of the TRANSACTIONS to each member of the Institute be discontinued, and that copies be furnished to all members who subscribe in advance at a price to be determined later, possibly $5 per year; the edition to be determined by the advance subscriptions received, with a reasonable allowance for stock to meet future demands.

The immediate occasion of the above action was the condition of the Institute's finances, caused by continuing all the activities of the Institute, at prevailing increased costs, without increasing the annual dues. The action was adopted after learning, through the Development Committee and through conference with the representatives of the various Sections at recent annual conventions, the attitude of the membership regarding the publications of the Institute.

The greatly increased cost of publishing the JOURNAL and TRANSACTIONS, together with the increased amount of suitable material available for publication, has rendered it necessary that the policy outlined above be now put into effect, and the following plan has been decided upon by the Board of Directors in connection with the 1921 and 1922 TRANSACTIONS.

1921 Transactions. This volume of the TRANSACTIONS is about to go to press, and the edition will be determined by the number of subscriptions received by January 1st, 1922, in response to the circular mailed to the membership November 12. The price of the TRANSACTIONS will be $3.00 *to the membership only.* (The regular price to non-members will still apply.)

1922 Transactions. Commencing with this volume, it has been decided to print each month in conjunction with the printing of the JOURNAL additional pages to be reserved and bound at the end of the year to form the volume of the TRANSACTIONS for those members who desire a file of papers and discussions in this form. The practise of printing discussions in the JOURNAL will be reestablished. The material to be contained in the TRANSACTIONS will be selected exactly as heretofore, the only difference in the volume being in the size of the pages, as pages from the JOURNAL will become identical with pages in the TRANSACTIONS, with the exception of a required change in folio numbers.

The edition of the TRANSACTIONS for 1922 will be based upon the number of members who make application therefor by January 1st, 1922, at the nominal price of $2.00 per year *to the membership only.*

The adoption of the above policy, resulting in the saving of a large portion of the expense caused by duplication of printing, will permit of the publication of additional desirable material, particularly relating to the activities of the Sections, and the further development of the JOURNAL in accordance with the policy decided upon in the fall of 1919, in response to the expressed wishes of the membership.

Each member who desires a bound copy of either the 1921 or 1922 TRANSACTIONS or both, is urged to make prompt application therefor, as only a limited number of surplus copies will be printed.

NOMINATION AND ELECTION OF INSTITUTE OFFICERS FOR 1922-1923

As provided in Section 19 of the Institute By-Laws, candidates may now be proposed for nomination for the offices to be filled at the next annual election in May, 1922, by the petition or by the separate endorsement in writing, of not less than twenty-five members. The petitions or separate endorsements must be in the hands of the Secretary not later than January 25, 1922. For the convenience of members, a form of petition has been prepared by the Secretary, and copies of it may be obtained upon application to Institute headquarters. Endorsements may, however, be made by letter if the form is not available. A member is not limited in the number of candidates he may endorse in this manner.

The officers to be elected are: A President and a Treasurer for the term of one year each, five Vice-Presidents for the term of two years each (one from each of the odd numbered geographical districts), and three Managers for the term of four years each.

The five odd numbered districts from which Vice-Presidents are to be chosen at the May 1922 election are as follows:

1. North Eastern: Connecticut, Maine, Massachusetts, New Hampshire, New York (exclusive of N. Y. Section territory), Rhode Island, Vermont.

3. New York City: Territory of the New York Section, Canal Zone, Porto Rico, all foreign countries (Canada excepted).

5. Great Lakes: Illinois, Indiana, Michigan, Wisconsin.

7. South West: Arkansas, Kansas, Missouri, New Mexico, Oklahoma, Texas.

9. North West: Idaho, Montana, Oregon, Utah, Washington, Alaska.

According to the revised Constitution, while one Vice-President must be elected from each of the five odd numbered districts, this does not debar members in one district, if they so wish, from nominating and voting for a candidate in another district. When the votes are counted the candidate for Vice-President having the largest vote in each district will be elected to that particular office for that district, irrespective of the fact that he may have polled a smaller number of votes than a candidate standing second in another district.

For the information of members the full text of revised sections of the Constitution and By-Laws applying to Officers, nominations, elections, etc., are printed below:

CONSTITUTION

SEC. 23. The officers of the INSTITUTE shall be a President, one Vice-President from each geographical district as defined in the By-Laws, twelve Managers, a Secretary and a Treasurer.

SEC. 24. The President, the Secretary and the Treasurer shall hold office for one year, the Vice-Presidents for two years and the Managers for four years. The President and Managers shall not be eligible for immediate re-election to the same office. No Vice-President or Manager who has served continuously in one or more offices, and whose combined terms shall have aggregated six years or more shall be eligible for immediate election to the office of Manager or Vice-President. At each Annual Meeting the President, the requisite number of Vice-Presidents to fill vacancies caused by expiration of terms, three Managers and the Treasurer shall be elected by the membership, and their terms of office shall commence on the first of August next succeeding their election.................

SEC. 24A. At the election of Vice-Presidents held in 1921 there shall be elected one Vice-President from each geographical district, those from the odd-numbered districts to serve for one year each, and those from the even-numbered districts two years each. All Vice-Presidents elected thereafter shall serve for two years each. In the event of a change in the geographical districts, the Vice-Presidents then in office shall complete their terms. In case of revisions of the geographical districts, the Board of Directors shall have the power to elect a Vice-President from each district not represented, to serve until the next election covering these districts.

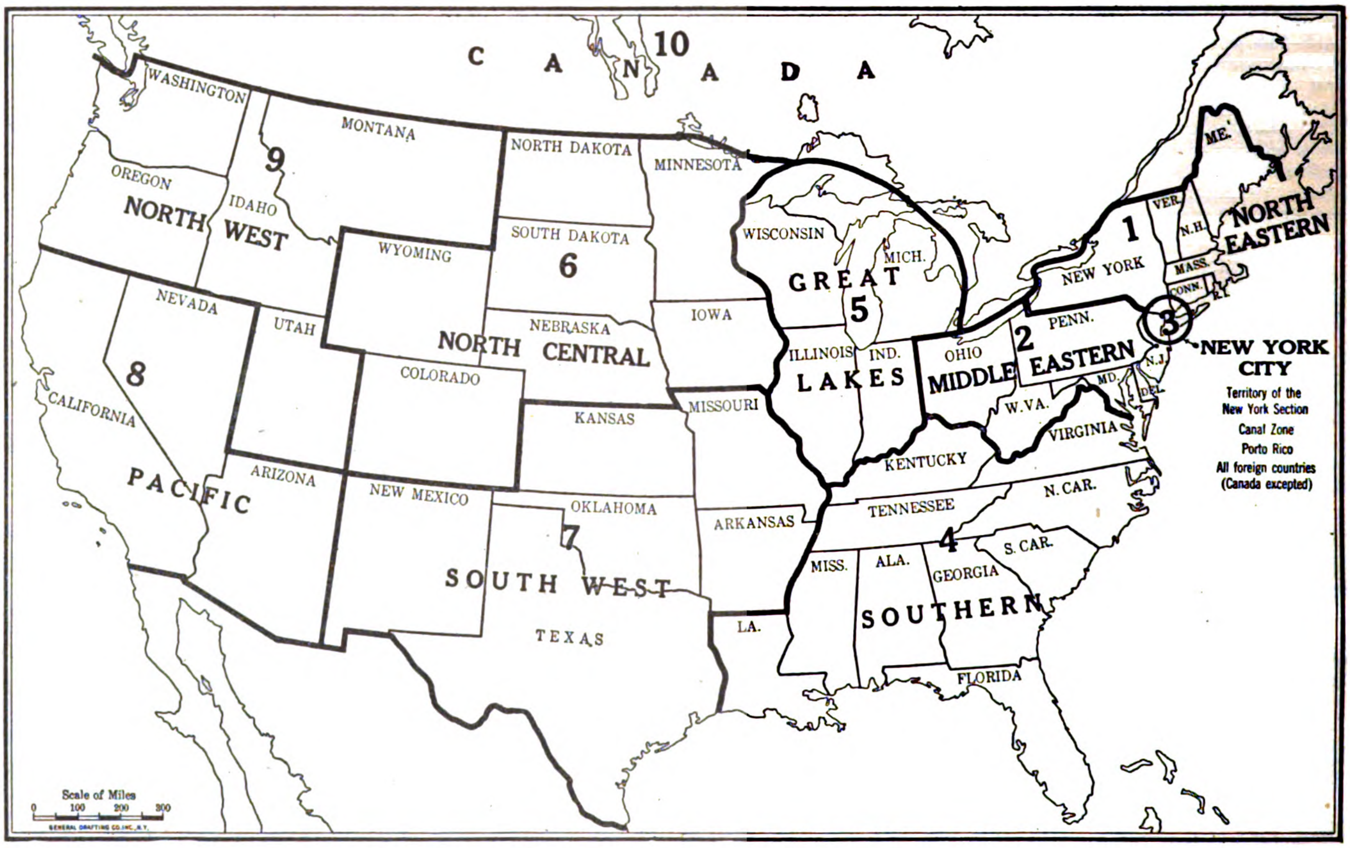
BY-LAWS

SEC. 19. In addition to the names of the incumbents of office the Secretary shall publish on the "form showing offices to be filled at the ensuing annual election in May provided for in Article VI, of the Constitution, the names, as candidates for nomination, of such members of the Institute as have been proposed for nomination for a particular office by the petition or by the separate endorsement of not less than twenty-five members, received by the Secretary of the Institute in writing by January twenty-fifth of each year; provided, however, that any candidate proposed for nomination by petition may withdraw his name by written communication to the Secretary, and any name so withdrawn prior to the printing of the form shall not be published.

The names of such candidates for nomination shall be grouped alphabetically under the name of the office for which each is proposed, and this by-law shall be reprinted prominently in the December and January issue of each year's JOURNAL and shall be reproduced on the form above referred to.

SEC. 21. There shall be ten geographical districts grouped as follows: (For the balance of this Section describing districts see paragraph preceding map.)

SEC. 21A. Should the territory of any Institute Section lie in more than one geographical district as defined above, then the entire territory of said Section shall be considered as belonging to the geographical district in which the headquarters of the Section are located.



Geographical districts into which the membership of A. I. E. E. has been divided for the purpose of electing Vice Presidents.

DR. J. B. WHITEHEAD AWARDED THE MONTEFIORE PRIZE

A triennial prize of 5000 francs given by the Foundation George Montefiore, Liege, Belgium, has been awarded to Dr. John B. Whitehead, Professor of Electrical Engineering, The Johns Hopkins University, Baltimore Md., for his research work in connection with a paper on "The Corona Voltmeter and the Electric Strength of Air," written by him in collaboration with a graduate student, T. Isshiki, and presented before the A. I. E. E. at the White Sulphur Springs Convention, June 1920. The prize is awarded by a jury of ten electrical engineers, of whom five are Belgian and five from other countries, for the best original work on scientific advancement or progress in the technical applications of electricity in all its branches.

AMERICAN ENGINEERING COUNCIL

NEXT MEETING OF COUNCIL IN WASHINGTON, JANUARY 5-6

The next meeting of the American Engineering Council of the Federated American Engineering Societies will be held in Washington, January 5 and 6. The date was determined at a meeting in New York City of the Council's Committee on Procedure, consisting of Calvert W. Townley, J. Parke Channing, Dexter S. Kimball, William McClellan and W. E. Rolfe. The meeting was attended by Dean Mortimer E. Cooley, the new president of the Council, who spent several days in New York familiarizing himself more intimately with national engineering policies and with L. W. Wallace, executive secretary of the Council, and members of the Committee on Procedure, working out details of Federation organization and development.

LAMPERT PATENT OFFICE BILL

In urging the passage of the Lampert Patent Office Bill, H. R. 7077, as announced in the November issue of the JOURNAL in the report of the September meeting of the Executive Board, American Engineering Council requests the support of the individual members of the Federated American Engineering Societies. Each member of the societies belonging to the Federated American Engineering Societies is requested to communicate with his Senator and personal Representative, urging the immediate enactment of the Lampert Patent Office Bill.

The report of the Committee on Patents, approved by the Executive Board at the September meeting, contained the following resolutions regarding this bill:

WHEREAS, American Engineering Council, of The Federated American Engineering Societies, representing 43,000 engineers in member and affiliated societies, is strongly convinced of the importance of the Patent Office to the maintenance of the manufacturing and agricultural welfare and supremacy of the United States and is deeply concerned over the present precarious and inefficient condition of the Patent Office, the said American Engineering Council represents to Congress that, while the Patent Office was in a most serious condition in 1919, when the need of its relief was first brought to the attention of Congress, the work of the Patent Office has increased 67.6 per cent, since that time, while the Patent Office force has only been increased 5.4 per cent, the salaries of examiners remaining at but 10 per cent more than they were in 1848, and the resignations of the Patent Office examiners have continued in increasing volume until but one-half of the examining force now consists of properly trained examiners; and

WHEREAS, the Lampert Patent Office Bill, H. R. 7077, provides the least increases in force and salaries which can possibly stop the retrogression of the Ptatent Office and enable it to make progress toward recovering an efficient condition, and by increases in the fees for patents, provides the funds necessary to enable the Patent Office to continue to be self-supporting;

NOW THEREFORE, AMERICAN ENGINEERING COUNCIL most urgently recommends to Congress the passage of the said Lampert Patent Office Bill, H. R. 7077.

The Patent Office has for years suffered from lack of proper support and as a result, American industry and commerce have been seriously retarded. The earnest support of the individual members of the Federated American Engineering Societies will materially aid in bringing about the passage of the Lampert Patent Office Bill which will enable the Patent Office to render the service demanded.

ELIMINATING WASTE IN ESTIMATING

A document on "Eliminating Waste in Estimating" has been produced through the cooperated work of the American Institute of Architects, The Associated General Contractors of America and the American Engineering Council. The report will prove of value to those interested in building and other construction projects, containing especially information to interest owners and investors, architects and engineers, and contractors. Anyone desiring a copy of this document may obtain one without charge upon application to The Federated American Engineering Societies, 719 Fifteenth St., N. W., Washington, D. C.

COMMITTEE ON ENGINEERING EDUCATION APPOINTED

One of the most important acts of the Committee on Procedure at its recent meeting was the appointment of a committee to work out a policy of engineering education. Col. A. S. Dwight of New York, Prof. Charles F. Scott of Yale and William W. Varney of Baltimore were appointed as members of this committee.

The committee was named as a result of a vote of the Executive Board "to appoint a Committee on Engineering Education to report what attitude the Federated American Engineering Societies should take."

The Board's decision to take up thoroughly the whole question of engineering education followed a discussion engendered by a resolution of Mr. Varney stating that "there is a feeling among engineers of this country that the engineering colleges have not expanded to meeting the present day demands in the most satisfactory manner." The resolution asked that the Federation appoint "a Committee on Education to consider broadly the training of the engineer and to report on desirable changes in present day engineering education to better prepare engineering graduates to take their proper places in the profession."

The University of Iowa has addressed a communication to the Executive Board recommending "that it is desirable to make an effort to have the American Engineering Council of the Federated American Engineering Societies establish standards of engineering education for engineering colleges of different grades and to rate the engineering colleges of the country in accordance with the classification adopted," and suggesting the establishment of five-year engineering courses, the first year of which should be given in the College of Liberal Arts and no specialization made except in the course in Chemical Engineering until the fifth year, the establishment of such five-year course being considered as a preliminary step toward the establishment of six-year courses.

Another communication to the Board on this subject was in the form of a paper on "The Status of Engineering Education" by Prof. John H. Dunlap, president of the Iowa Engineering Society.

The general consensus of opinion among the members of the Board was that there was a number of other organizations more directly affected by and concerned with these matters, that were giving consideration to them, and hence, it was not within the purview of the Federation to take them up. But since the subject had been broached and since written communication had been received suggesting that the Federation should be active in such things, it was decided to institute appropriate inquiry through a special committee.

Col. Dwight, Prof. Scott, and Mr. Varney are all members of the Executive Board and have taken a deep interest in engineering education policies.

PERSONAL MENTION

JOEL S. LAWSON recently left R. Thomas & Sons Company of New York to become general manager of the Memco Engineering & Mfg. Company, Inc., New York.

JOHN H. EBAUGH has left the Allis-Chalmers Manufacturing Company of Los Angeles to become instructor in the electrical department of the Fresno Technical High School, Fresno, Cal.

CHAS. H. MATTHEWS is with the Smith Green Company of Worcester, Mass., as sales engineer. He was until recently an electrical engineer with the Westinghouse Electric & Mfg. Company.

HOWARD W. THOMAS has left Washington D. C., to become inspector of electrical material in the Plant Department of the Boston Navy Yard.

ROBERT H. HULL has become instructor of electrical engineering in the University of Colorado, Boulder, Colo. He was previously with the Great Western Sugar Company, of Denver.

PERRY L. HARRIS has left the Federal Shipbuilding Company, Kearny, N. J., to become connected with the Newberry Electric Corporation of Los Angeles, Cal.

C. F. SCHOONMAKER, who was assistant engineer with the Quaker Oats Company, Chicago, is now with The Iowa Railway & Light Company, Cedar Rapids, Iowa.

CHAS. H. YOST, formerly with the General Electric Company, has become located with the Niagara, Lockport, and Ontario Power Company, Buffalo, N. Y.

JAMES DEALEY has severed his connections with the Crescent Pure Milk Company of Winnipeg, Man., and is located with the Central Repair Company of that city.

HERMAN W. BOCHER has left his work as instructor of electrical engineering in the School of Engineering, Milwaukee, to become power dispatcher with the Illinois Traction System, Peoria, Ill.

CHAS O. GIBBON, formerly research engineer with the Fessenden Engineering Laboratory, Boston, has become connected with the American Telephone & Telegraph Company, New York, as assistant engineer.

CARL H. DUNLAP has become head of the electrical engineering department of the American School of Correspondence, Chicago, having left his position as chief inspector with Roth Brothers & Company, of Chicago.

DENIS V. PAFINEAU has accepted a position in the method engineering department of the Western Electric Company, Inc., New York. He was previously a telephone engineer with the Northern Electric Company, Ltd., Montreal.

ERNEST R. FELLOWS, who was with the General Electric Company as inspector of hull material for the U. S. Navy, has left Schenectady to become superintendent of construction for the Associated Telephone Company, Long Beach, Cal.

F. T. COUP has been appointed district manager of the Cincinnati office of the Wagner Electric Manufacturing Company. He has been connected with the Wagner Company for a number of years, being formerly in charge of the Milwaukee office.

ALEX J. LARDNER, formerly electrical inspector with the Public Works Department of New Zealand, has become managing director of The Union Electrical Company, Ltd., Timaru, N. Z.

GEO. LEE HOADLEY is now head of the department of electricity in the School of Engineering, Milwaukee, Wis. Until this fall he was teaching in Washington State College at Pullman, Wash.

H. P. SPARKES, formerly with the Westinghouse Electric & Manufacturing Company, E. Pittsburgh, has become located in the meter department of the West Penn Power Company, Pittsburgh.

T. W. CARRAWAY has resigned his position with the government as chief engineer, U. S. Government Repair Unit No. 304, to go into business, forming the Carraway Engineering Company of San Antonio, Tex., specializing on mechanical refrigeration.

WM. HOWARD GROVE, formerly with the Republic Railway & Light Company, New York, has entered the electrical engineering department of the Cleveland Electric Illuminating Company of Cleveland, Ohio.

ARTHUR C. STANSFIELD, of the Commonwealth Edison Company, Chicago, is in England on a six months' vacation. He expects to return to the United States or Canada next spring. His present address is No. 24 Ashley Lane, Moston, Manchester, Eng.

OSWALD DALE has accepted the position of general manager of the Pittsburgh Insulating Company, Pittsburgh, Pa. Until recently he was connected with the Irvington Varnish & Insulator Company, Irvington, N. J., as vice-president and general manager.

G. W. SOENGEN of G. W. Soengen & Company, St. Louis, a company recently organized by him, has purchased the entire survey notes and records of both B. E. Johnson and Jos. W. Wilson, surveyors and civil engineers of St. Louis County, Mo. The company will carry on electrical, civil, and mining engineering.

F. T. WRIGHT, who recently resigned his position as assistant chief mechanical engineer of the Royal Siamese State Railways, has been appointed chief electrical engineer of the Bombay, Baroda and Central India Railway Company with headquarters in Bombay. The company proposes to electrify the Bombay suburban lines.

A. W. BATES has been appointed stores manager of the Western Electric Company at Detroit. Mr. Bates has been connected with the company for twelve years, entering the telephone department at New York, where eventually he became head of the service department. In 1918 he was sent to New Haven as manager.

EMERSON A. ARMSTRONG is now located with the Public Service Company of Northern Illinois, in charge of power sales for the Joliet district. Mr. Armstrong some months ago left the Lincoln Motor Company, of Detroit, where he was assistant superintendent of construction and maintenance, and has since been engaged in special design and lecture work at the Michigan State College.

WM. A. WINTER, who has been in Europe to obtain information regarding X-ray cancer treatment, returned recently and will start in business for himself. Mr. Winter has been connected with the Kny-Scheerer Corporation of America, New York City, for thirty years, devoting his full time since 1895 to the development of X-ray apparatus. He joined the Institute during the past year.

HAROLD B. FISK was recently appointed manager of the Walsh Plate & Structural Works, Ltd., at Drummondville, Que. Mr. Fisk has seen service with several large Canadian power companies since coming to Canada from England in 1907, having been previous to his present appointment superintendent of the Drummondville Division of the Southern Canada Power Company. He became a member of the Institute in 1919.

A. W. K. BILLINGS has returned from Barcelona, Spain, to act as construction manager for the English and Canadian interests controlling large public utility companies in Mexico, Brazil and Spain, and as vice-president of the Canadian Engineering Agency, Inc., New York City. During the war Mr. Billings was in charge in Europe of naval aviation construction work ashore. He was promoted to the rank of Commander in the Naval Reserve and was awarded the Navy Cross and the Legion of Honor.

EDWARD M. ELIOT has been appointed assistant to the vice-president of the Underfeed Stoker Company of America, having resigned as service manager for the Diamond Power Specialty Company of Detroit. Mr. Eliot was engaged in power plant design and construction for eight years with the Oregon Electric Railway Company, The Electric Bond & Share Company, and others; and for the past seven years he has specialized in the organization of service work and repair sales. He is a graduate of Massachusetts Institute of Technology.

ARTHUR LUCIAN WALKER, professor of metallurgy in the School of Mines, Engineering and Chemistry of Columbia University, has been elected a member of the Board of Engineering Foundation. He succeeds the late Dr. Joseph W. Richards, representing the American Institute of Mining and Metallurgical Engineers on the Board. Prof. Walker is internationally known as an inventor and a teacher. One of his inventions was a mechanical casting machine which revolutionized methods used for casting copper into refined shapes, and another was a new system for electrolytic copper refining tank room arrangement, which has been largely installed in copper refining plants built since the invention in 1902.

OBITUARY

ROBERT MCKAY, barrister at law and member of the firm of McKay, Dods and Grant, Toronto, Ontario, died of throat trouble on November 6th at the Wellesley Hospital after an illness of less than a week. Mr. McKay was a graduate of the Toronto Collegiate Institute and the University of Toronto. He was called to the bar in 1891 and has been connected as counsel with many prominent railroad and hydroelectric litigations and inquiries. He joined the Institute in 1904.

WARREN H. FISKE, a Fellow of the Institute, died September 8, 1921, of acute appendicitis. Mr. Fiske had made his home in Marblehead, Mass., for the past year and a half. His engineering experience was largely in the field of steam and hydraulic power plants, including seven years as electrical engineer with the Metropolitan Street Railway, New York City; four years as resident engineer in Toronto connected with the Niagara Falls power substations and the steam plants in Toronto and Winnipeg, Man.; six years as chief engineer of the Mexican Light and Power Company and Mexico Tramway Company at Mexico City; and two years as general superintendent of the Barcelona Traction Light & Power Company in Spain. Previous to the war he was engaged in work at the Ammonia Nitrate Plant at Muscle Shoals, Ala., and during the war was in government service at Boston, in the Bureau of Aircraft Production of the War Department. Mr. Fiske was born in Somerville Mass., in 1869, and was a graduate of Tufts College, 1891.

LEON H. SCHERCK died at his home in Poughkeepsie, N. Y., on November 16, 1921. Mr. Scherck was born in New Orleans, La., in 1875, receiving his education at Tulane University, from which he received the degree of Mechanical Engineer in 1896. He started to work with the Louisana Electric Light Company, which was afterwards absorbed by other companies. In 1903 he left New Orleans for New York, later becoming connected with the Central Hudson Gas & Electric Company of Poughkeepsie, with which he remained until the time of his death. Mr. Scherck joined the Institute in 1906.

RAYNOR M. BEDELL, of Montclair, N. J. died on November 5, 1921, of tetanus, developing from a cut by glass on his foot three weeks previous. Mr. Bedell had been associated with the later Peter Cooper Hewitt as electrical expert. He was born in Montclair in 1880, and was graduated from Cornell University in 1902, joining the Institute the following year. He is survived by a brother Prof. Frederick Bedell of Cornell a former vice-president of the Institute.

JAMES HOWARD BECKER, formerly assistant instructor in the electrical engineering laboratory of the Massachusetts Institute of Technology, died suddenly on October 22 at Oberlin. Mr. Becker, just 24 years old, had been a student at the Massachusetts Institute of Technology for the past six years, continuing his studies there while a member of the faculty. He had recently accepted a position, however, with the Sandusky Foundry & Machine Company. His death occurred while he was on his way to a football game; apparently fainting, he could not be revived. He was buried in Clyde, Ohio, his birthplace.

CHARLES R. CROSS, professor emeritus of physics of the Massachusetts Institute of Technology and a charter member of the A. I. E. E., died November 16 at his home in Brookline, Mass. Prof. Cross was born in Troy, N. Y., in 1848, and was graduated from the Massachusetts Institute of Technology in 1870. The next year he became an assistant in physics in that institute, with which he has been connected ever since, being appointed professor of physics, then director of the Rogers Laboratory, and finally retiring a few years ago with the title of professor emeritus. It was largely due to his foresight and recognition of the increasing importance of electricity in modern life that the Massachusetts Institute of Technology offered the first degree given in an electrical engineering course in the United States. As a teacher Prof. Cross held to the highest standards of student training. He was an authority on sound, and aided greatly in the development of the telephone. Many contributions from him have been published, including the article on "Telephony" in the Encyclopedia Britannica. Besides being a member of the A. I. E. E. since 1884, Prof. Cross was a fellow of the American Academy of Arts and Sciences, a member of the American Physical Society, British Association for the Advancement of Science, and past-chairman of the American Association for the Advancement of Science and of the Rumford Fund Committee.

ALFRED ROLAND VAN HORN died on October 25 after a protracted illness of nearly two years. Mr. Van Horn was an inventor of electrical appliances, one of which was an automatic

control for isolated power plants. He was engaged in the manufacture of this machine with the Trumbell Electric Manufacturing Company of Plainville, Conn., until his illness caused him to stop active work. Born in Philadelphia in 1886, Mr. Van Horn attended the Pennsylvania State College and Drexel Institute for two years each. After three years of engineering experience in a partnership, he started his experimental work in 1911, and continued in that line, becoming in 1919 an engineer with the Trumbell Company, which had bought the manufacturing right to his device. During the war ill health kept Mr. Van Horn from passing the physical examination for the army, but he did construction work at the Hog Island navy yard and also at one of the stations of the Philadelphia Electric Company. He joined the Institute early in 1920.

WILLIAM EDGAR BAKER died suddenly of heart disease at 50 East 58th Street, New York City, on November 7, 1921. Prominent in both the civil and electrical engineering fields, Mr. Baker had retired from active business in recent years. He was born at Springfield, Mass., in 1857, and was graduated from Lafayette College in 1877. He then entered the service of the Canadian Pacific Railroad under such conditions of hardship that few survived, but soon showed his ability. In 1884 he left this to become resident engineer for the International & Great Northern Railway, in Texas. Four years later he began his career as electrical engineer, accepting appointment as superintendent in charge of the installation of electricity on the West End Street Railway System of Boston. From 1892-94 he designed and built the Columbian Intramural Railway in Chicago, a work which brought him into prominence both in this country and in Europe. During the next five years he was general manager and chief electrical engineer of the Metropolitan West Side Elevated Railroad in Chicago. In 1899 he came to New York to accept the same position with the Manhattan Elevated Railroad, operating the railroad as its general manager until he resigned and opened an office in New York as consulting engineer. He was a trustee of Lafayette College, and deeply interested in its welfare. He joined the Institute in 1901.

ENGINEERING SOCIETIES LIBRARY

The library is a cooperative activity of the American Institute of Electrical Engineers, the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers and the American Society of Mechanical Engineers. It is administered for these Founder Societies by the United Engineering Society, as a public reference library of engineering and the allied sciences. It contains 150,000 volumes and pamphlets and receives currently most of the important periodicals in its field. It is housed in the Engineering Societies Building, 29 West Thirty-ninth St., New York.

In order to place the resources of the Library at the disposal of those unable to visit it in person, the Library is prepared to furnish lists of references to engineering subjects, copies or translations of articles, and similar assistance. Charges sufficient to cover the cost of this work are made.

The Director of the Library will gladly give information concerning charges for the various kinds of service to those interested. In asking for information, letters should be made as definite as possible, so that the investigator may understand clearly what is desired.

The library is open from 9 a. m. to 10 p. m. on all week days except holidays throughout the year except during July and August when the hours are 9 a. m. to 6 p. m.

BOOK NOTICES (OCT. 1-31, 1921)

Unless otherwise specified, books in this list have been presented by the publishers. The Society does not assume responsibility for any statements made; these are taken from the preface or the text of the book.

All the books listed may be consulted in the Engineering Societies Library.

AMERICAN ELECTRICIAN'S HANDBOOK.

By Terrell Croft. Second edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1921. 823 pp., illus., 7 x 4 in., fabrikoid. $4.00.

A collection of the information needed by wiremen, contractors, linemen, small plant superintendents, operators and construction engineers, in selecting and installing and operating commercial electrical apparatus for the performance of various duties. This edition has been carefully revised throughout, obsolete matter discarded, new matter added and many parts rewritten.

ELECTRICAL TRANSMISSION OF PHOTOGRAPHS.

By Marcus J. Martin. Lond. and N. Y., Sir Isaac Pitman & Sons, Ltd., 1921. 136 pp., illus., diagrs., 7 x 5 in., cloth, $2.00.

A brief description of the various systems devised for the transmission of photographs over metallic conductors, and of the principles underlying them. Chapters on television and on the wireless transmission of photographs are added, as is also one containing full working drawings for an experimental transmitting or receiving machine.

FIRST PRINCIPLES OF ELECTRICAL TRANSMISSION OF ENERGY.

By W. M. Thornton. Lond. and N. Y., Sir Isaac Pitman & Sons, Ltd., 1921. (Technical primer series.) 116 pp., diagrs., 6 x 4 in., cloth. $.85.

This book is the substance of a course of six lectures given to an audience of practical engineers and students. The subject is presented from the viewpoint of the electron, not yet usual in engineering literature.

MODERN CENTRAL STATIONS.

By Charles W. Marshall. Lond. and N. Y., Sir Isaac Pitman & Sons, Ltd., 1921. (Technical primer series.) 115 pp., illus., 6 x 4 in., cloth. $.85.

A brief description of the principal features of British central station practise, intended for young engineers. Includes the coal and ash handling plant, boiler house, engine room, switch and protective gear, plant operation and testing.

BERICHTER UND ABHANDLUNGEN DER WISSENSCHAFTLICHEN GESELLSCHAFT FUR LUFTFAHRT. (Beihefte zur "Zeitschrift Flugtechnik und Motor luftschiffahrt.") 4. Heft, April 1921. Munchen, R. Oldenbourg. 81 pp., illus., 12 x 9 in., paper. 32 M.

This supplement contains the proceedings of the sixth meeting of the Society, at Charlottenburg, 15 October, 1920. In addition to the official actions of the meeting, it contains the technical papers presented, which treat of the relation between the design of power plants for aircraft and safety in flight. The results of research in aerology and atmospheric electricity by flights, the formation of eddies by planes and advances in space telegraphy and telephony.

GESUNDHEITS-INGENIEUR.

Festnummer, Juli 1921. Munchen, R. Oldenbourg. 52 pp., 13 x 10 in., paper. 10 M.

This "Festnummer" was issued to commemorate the tenth convention of heating and ventilating engineers, at Munich in July, 1921. Papers on the heating and ventilating plant of the new Rathaus at Barmen, methods of utilizing waste heat, the development of electric heating in Switzerland and an extensive system of central heating are included, together with others on the general subject.

TEMPERATURE INDICATING AND CONTROLLING SYSTEMS.

By Franklin D. Jones. First edition. N. Y., Industrial Press, 1921. 59 pp., illus., 9 x 6 in., paper. $.50.

A general review of the application of thermoelectric pyrometers to the heat treatment of steel parts. The methods and apparatus used in various plants to indicate, control and record temperature are described and illustrated.

GENERAL PHYSICS.

By Ervin S. Ferry. N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall, Ltd., 1921. 732 pp., illus., 8 x 5 in., cloth. $4.00.

This book is designed for those students who require a coordinated elementary course in the fundamental principles, the methods and the industrial applications of physics in the early part of their college career. The laws selected for inclusion in the text are those that occur frequently in the ordinary affairs of life and those widely applied in the arts. Hypotheses still in controversy are omitted, and only simple mathematics is used.

WITHIN THE ATOM.

By John Mills. N. Y., D. Van Nostrand Co., 1921. 215 pp., illus., 8 x 5 in., cloth. $2.00.

This volume is intended for readers who wish to obtain a familiarity with the basis of modern physical science. Without mathematical formulation it deals with modern theories as to matter and energy, emphasizing the granular structure and electrical nature of matter, and the apparently corpuscular character of energy. The reader need have no previous knowledge of electricity, mechanics or chemistry.

MECHANICS.

By James E. Boyd. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1921. 417 pp., diagrs., 9 x 6 in., cloth. $3.50.

Intended to give a working knowledge of the principles of mechanics and to supply a foundation upon which intelligent study of the strength of materials, stresses in structures, machine design and other more technical courses may rest. In the development of the subject, emphasis is put upon the physical character of the ideas expressed.

ANALYTICAL MECHANICS FOR ENGINEERS.

By Fred B. Seely and Newton E. Ensign. N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall, Ltd., 1921. 486 pp., diagrs., 9 x 6 in., cloth. $4.00.

The aim in this book has been to make the principles of mechanics stand out clearly, to build them up as much as possible from common experience, to apply the principles to concrete problems of practical value, and to emphasize the physical rather than the mathematical interpretation of them. Statics, kinematics and kinetics are included, the two latter being developed with regard for the increasing importance of dynamics to engineers. The treatment of kinetics has been restricted to the more common types of motion found in engineering practise, but these motions have been treated more fully than is usual in elementary texts.

DRAWING ROOM PRACTISE.

By Frank A. Stanley. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1921. 253 pp., illus., 9 x 6 in., cloth. $2.50.

This book deals with the making of drawings, from the simplest constructions to complete assembly and working drawings of various classes. It is based on experience in a number of leading American and European drawing rooms, and in teaching students. The difficulty in visualizing the work represented by a drawing, which many students undergo, has led the author to present photographs of the objects represented by the working drawings discussed in the book.

LESSONS IN LETTERING. BOOK 1.

By Thomas E. French and William D. Trumbull. 40 pp., 6 x 9 in., illus., paper. $.35.

The first volume of this series is devoted to the letter commercially known as Gothic, and widely used by engineering draftsmen. A series of graded exercises is given.

STEAM BOILERS.

By Terrell Croft. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1921. 412 pp., illus., 8 x 6 in., cloth. $4.00.

This book has been compiled for men of little schooling who wish to inform themselves about the construction and operation of steam boilers, especially those preparing for examinations for engineers' licenses. It treats of the functions, history and modern types of boilers, boiler construction, accessories, steam generation, superheating, fuels, settings, furnaces, feed-waters, boiler-room equipment, inspection and management, in clear, simple language.

PNEUMATIC CONVEYING.

By E. G. Phillips. Lond. and N. Y., Sir Isaac Pitman & Sons, Ltd., 1921. (Technical primer series.) 108 pp., illus., 6 x 4 in., cloth. $.85.

A general survey of the information available on machinery and methods for handling coal, ashes, grain and other heavy solids, with brief references to air-lift pumping, vacuum cleaning, etc.

MODERN BUILDING SUPERINTENDENCE AND THE WRITING OF SPECIFICATIONS.

By David B. Emerson. N. Y., Charles Scribner's Sons, 1921. 247 pp., 7 x 4 in., cloth. $1.75.

This volume is intended to aid the young engineer in superintending construction and in writing building specifications. The author outlines, step by step, the duties of the superintendent during the erection of a typical modern twenty-story office building, calling attention to the matters that must be watched. In similar fashion, he outlines the proper procedure in writing specifications for a small dwelling.

TIME STUDY AND JOB ANALYSIS.

By William O. Lichtner. N. Y., Ronald Press Co., 1921. 397 pp., illus., 9 x 6 in., cloth. $6.00.

The author attempts to explain the practical application of these methods in simple, non-technical terms, as might be done in a series of conferences with an executive charged with the responsibility of decision. The book first presents a general review of the principles of job standardization and their application to time study and job analysis. The organization of a staff to carry out the work is then described in detail. This is followed by a detailed description of the technique of the subject, and the book closes with a consideration of the relation of job standardization to industrial problems.

THE PSYCHOLOGY OF INDUSTRY.

By James Drever. N. Y., E. P. Dutton & Co., 1921. 148 pp., 8 x 5 in., cloth. $2.50.

Dr. Drever discusses such topics as the intelligence and vocational fitness of the worker, scientific mental engineering, the factors determining efficiency of work, fatigue, economy of movement, advertising and salesmanship. Upon these and similar matters he sets forth what has been done by the psychologist, in language understandable by the ordinary man. A special effort is made to adhere to the psychological point of view and to emphasize principles rather than details of results.

COMMERCIAL COMMODITIES.

By Frank Matthews. Lond. and N. Y., Sir Isaac Pitman & Sons, Ltd., 1921. 319 pp., illus., 9 x 6 in., cloth. $4.00.

The purpose of this book is to give a not too detailed idea of the important raw or semi-manufactured articles used in trade. A wide variety of materials is described, including the mineral and metallurgical products, foodstuffs, drugs, textiles, oils and fats, plant juices, etc.

ECONOMIC ASPECTS OF THE GREAT LAKES—ST. LAWRENCE SHIP CHANNEL.

By Roy S. MacElwee, Alfred H. Ritter. N. Y., The Ronald Press Co., 1921. 291 pp., maps, tables, 9 x 6 in., cloth. $4.00.

This work is a study of the local and national advantages to be gained from opening the Great Lakes to ocean traffic. It attempts to coordinate the information on the commercial and economic aspects of the proposed ship channel, as presented at the hearings held throughout the country by the International Joint Commission and to present the vital facts affecting the advisability of the construction of the proposed improvement.

INDUSTRIAL AND POWER ALCOHOL.

By R. C. Farmer. Lond. and N. Y., Sir Isaac Pitman & Sons, Ltd., 1921 (Technical primer series.) 110 pp., diagrs., 6 x 4 in., cloth. $.85.

This is a brief, non-technical account of the important uses of alcohol, other than as a beverage, suited to the needs of engineers requiring a handy survey of the subject.

SECTION AND BRANCH MEETINGS

PAST SECTION MEETINGS

Akron.—October 28, 1921. Preparatory to the inspection of the Laboratory of the Engineering Department of the Municipal University of Akron, short addresses were made by several members of the faculty. A trip was then made through the Laboratory and the various pieces of apparatus demonstrated by the students. Attendance 60.

Altanta.—October 27, 1921, Chamber of Commerce Building. Dr. J. W. Landrum, assisted by Dr. Allen H. Bunce, both X-Ray experts of Atlanta, gave a very interesting illustrated lecture on the use of X-Ray, diagnosis and treatment of diseases. Mr. Ralph W. Fitting, a visiting engineer from New York City, gave a very instructive talk on the use of radium and its application to diseases. A moving picture, exhibiting the various stages in the manufacture of X-Ray apparatus and also fluoroscopic picture of the bones of the human body, was shown. Attendance 125.

Baltimore.—October 7, 1921, Engineers Club of Baltimore. Joint meeting of Baltimore Sections of A. S. M. E. and A. I. E. E., and the Engineers Club of Baltimore, preceded by a dinner. Paper: "The Application of Electricity to the Drive of Merchant Ships." Speaker: Mr. E. D. Dickinson, of the Marine Department, General Electric Company. Mr. W. C. Watson also presented a paper dealing with the equipment on the new electrically driven battleship *Maryland*. A number of pictures showing the details of the equipment used in connection with the electric drive of merchant ships and in connection with the drive of the battleships *New Mexico* and *Maryland*, were shown. Both papers were discussed by Commander J. O. Fisher and Commander Miles A. Libbey. Attendance 150.

Boston.—October 28, 1921, Engineers Club of Boston. Subject: "Telephone Transmission Between Cuba and Catalina." Speaker: Mr. H. S. Osborne, of the American Telephone & Telegraph Company. Mr. Osborne spoke of the details of telephone transmission over long distances and showed the various long-distance circuits available in the United States. The particular interest of the evening was a description of the complete circuit as indicated by the title, transmissions being affected under water by cable from Havana to Key West, then over the transcontinental line, and the final link completed by radio from Los Angeles to Avalon. Attendance 100.

Chicago.—October 26, 1921, Fullerton Hall. Joint meeting with the Western Society of Engineers. Subject: "The Frontiers of the Universe—An Evening with the Stars." Speaker: Professor F. R. Moulton, of the University of Chicago. The talk was illustrated with lantern slides. Attendance over 500.

Cincinnati.—October 13, 1921, Assembly Hall, Union Gas & Electric Co. A paper was read on the subject of "Analysis of Economic Losses Due to Poor Power Factor and Basic Meterable Factors" by Messrs. J. F. Doran, J. B. Hodtum and R. C. Fryer. The kv-a. meter was explained by D. G. Angus. An elaborate demonstration was made by measuring loads at different power factors. It was also shown how power factor could be corrected by synchronous machines if properly adjusted. Attendance 70.

November 10, 1921, Assembly Hall, Union Gas & Electric Co. Subject: "Street Lighting." Speaker: Mr. L. A. Anderson, of Nela Park, Cleveland. The subject was illustrated with lantern slides. Attendance 50.

Cleveland.—October 18, 1921, Elec. League Rooms. Paper "The Lead Storage Battery and Its Application to the Automotive Starting and Lighting Field." Speaker: Mr. T. R. Cook, of the Westinghouse Union Battery Co. The speaker outlined the particular problems encountered and explained the reason for various details of design. Attendance 83.

Connecticut.—October 25, 1921, Dunham Laboratory, Yale University. Subject: "The Status and Meaning of Superpower." Speaker: Professor L. P. Breckenridge, of Yale University. The speaker expected that the report of the Superpower Commission would be ready by November 1, and that it would point to a possible saving of $250,000,000 a year through the conservation of some 50,000,000 tons of coal, the area considered being the North Atlantic Seaboard. To effect such a saving, there is proposed a scheme of utilizing highly efficient steam and hydroelectric stations to develop the bulk of the energy requirements of the area, transmitting the same by high-voltage lines to the present electric utilities and railroads for local distribution. Mr. Sidney Withington, Electrical Engineer of the N. Y. N. H. & H. R. R. drew a comparison of the various methods of utilizing electrical energy for traction purposes. All the American practise was included, especial emphasis being laid on the three-wire single-phase system perfected by the local railroad. The talk was illustrated by slides. A striking example of the rapid growth of the electric power, industry was brought out by Mr. H. R. Westcott, of Westcott & Mapes, consulting engineers. The widely different requirements imposed upon the power plants of electric public utilities and of industrial plants were contrasted by Mr. P. L. Smith, Plant Engineer of the Winchester Repeating Arms Company. Attendance 80.

Denver.—October 22, 1921, Gas & Electric Building. Subject: "Industrial Heating by Electricity." Speaker: Mr. H. Fulwider. The talk was illustrated by lantern slides, showing many of the uses to which heating by electricity is put in all kinds of industries. Attendance 28.

November 2, 1921, Denver Gas & Electric Building. Subject: "Manufacture and Application of Arc Welding Electrodes." Speaker: Mr. Charles A. McCune. The talk was illustrated by moving pictures. Attendance 54.

Detroit-Ann Arbor.—October 14, 1921, Detroit Board of Commerce. The meeting was preceded by the annual Fall dinner. Subject: "Affiliation of Technical Societies of Detroit." Speaker: Mr. A. A. Meyer. The progress of the Affiliation to date was reviewed, and some of the broader aspects of such a society, and the advantage to the A. I. E.E. of belonging, were brought out. Attendance 36.

Fort Wayne.—October 27, 1921, Decatur, Indiana. The meeting included an inspection trip through the Holland-St. Louis Sugar Company's factory. The members assembled at the Interurban Station at 5:30 and boarded a special car which had been provided through the courtesy of the Indiana Service Corporation, the members being the guests of Mr. S. W. Greenland while en route. Supper was served at the Hotel Murray about 6:45, where the Section was welcomed to Decatur by officials of the Sugar Company. After supper Messrs. Carmody and Simpson, of the Company, spoke briefly on the specific problems of the local industry, the most troublesome one being the disposal of certain refuse which has heretofore caused considerable concern in Fort Wayne by contamination of the water of the St. Mary's river. These men strongly emphasized the point that the most modern apparatus obtainable has been installed which will effectively remedy this situation. After this preliminary meeting the members were taken through the factory in small groups and explained in detail the process of extracting sugar from beets, and the operations from washing

the raw beet to sacking the refined product were observed. Attendance 71.

Kansas City.—October 21, 1921. Subject: "Storage Batteries." Speaker: Mr. William Beck, of the Engine Electric Storage Battery. Attendance 23.

Los Angeles.—October 25, 1921, Polytechnic High School Auditorium. Subject: "The Industrial West." Speaker: Mr. Robert Sibley, Vice-President of the Pacific Geographical Division. The talk was illustrated by lantern slides showing the various uses to which electric power is now put, and numerous figures were presented showing to how much greater extent electricity was used per capita in the eleven western states than in the rest of the country. Attendance 85.

Madison.—November 9, 1921, Engineering Building, University of Wisconsin. Paper: "Illustrated Description of the Lakeside Power Plant of the Milwaukee Electric Railway and Light Company at Milwaukee." Speaker: Mr. G. G. Post, Electrical Engineer of the Company. Attendance 65.

Milwaukee.—October 19, 1921, Milwaukee Athletic Club. Paper: "Industrial Labor and Employment Situation." Speaker: Professor John R. Commons, University of Wisconsin. Attendance approximately 100.

Minnesota.—October 24, 1921, Auditorium of Chemistry Building, State University, Minneapolis. Paper: "Theory of Relativity." Author: Professor W. F. G. Swann, Department of Physics, University of Minnesota. The paper was illustrated with numerous models and sketches. Attendance 225.

New York.—November 14, 1921. A joint meeting of the Metropolitan Sections of the four national societies of Civil, Mining, Mechanical and Electrical Engineers was held at Institute headquarters on the evening of November 14. The subject under discussion was "The Great Lakes-St. Lawrence Ship Canal and Power Project." Dr. W. L. Saunders opened the meeting and read a letter from Chas. T. Gwynne of the Chamber of Commerce of New York asking for a second meeting at which the opposition to the project could be presented. Dr. Saunders then referred his invitation to Gov. Miller of New York and others to attend and present their side. He then introduced Julius Barnes of Duluth, formerly U. S. wheat director, who took charge of the meeting. He outlined at length the various engineering and economic features of the entire project. Mr. Barnes then introduced H. I. Harriman of Boston, Chairman of the Massachusetts State Commission on Foreign and Domestic Commerce. Mr. Harriman devoted his talk chiefly to the question of the expense involved in building and operating the canal and showed that the proposed hydroelectric development in connection with the large dam to be constructed near Cornwall would provide for the generation of 1,700,000 h. p., the income from the sale of which would over balance fixed charges, operating and maintenance expenses. He also outlined the effect of the canal on foreign and domestic commerce and on the cost of wheat and other exports.

Gov. Allen of Kansas followed Mr. Harriman and covered the subject from the viewpoint of the sixteen states of the middle west most interested in obtaining the canal for the export of their food products direct in ocean going ships. He stated that the saving on wheat alone at 5 cents per bushel during the past year could have paid for the entire project. Gov. Allen then took the objections advanced by Gov. Miller in a speech at Buffalo and answered them individually, pointing out the extremely congested condition of the various seaports and the relief which the canal would bring.

Former Gov. Harding of Iowa followed Governor Allen and was in turn followed by Dr. McElwee of Georgetown University, formerly director of the Bureau of Foreign and Domestic Commerce.

Panama.—October 23, 1921, All America Cables Building. Paper: "The Submarine Cable." Authors: Messrs. M. L. Cordua and H. Pescod. Attendance 52.

Philadelphia.—October 10, 1921. The meeting was preceded by a dinner at the Engineers' Club. Subject: "Military Intelligence." Speaker: Major J. S. Stewart-Richardson. Attendance 76.

Portland.—October 12, 1921, University Club. Subject: "What is Relativity." Speaker: Professor A. A. Knowlton, Department of Physics, Reed College. The speaker held the keenest attention of the audience for over an hour with a very interesting and vivid explanation of the fundamentals of the Einstein Theory of Relativity. Attendance 100.

Providence.—November 4, 1921, Providence Engineering Societies Rooms. Subject: "Manufacture of Insulated Wire and Cable." Speaker: Mr. W. I. Middleton, Electrical Engineer for the Simplex Wire and Cable Co. The talk was very well illustrated with slides covering all the processes and machines used in applying the insulation and protective coverings and in the making of cable. Attendance 75.

Rochester.—October 28, 1921. Subject: "State Licensing of Professional Engineers." Speaker: Mr. Virgil S. Palmer, Industrial Engineer of the Eastman Kodak Company. The speaker gave a very interesting talk on the history, work and purpose of the New York State License Law, going fully into the details of the law, giving definitions and application of the law. His talk covered the subject of licensing of professional engineers very thoroughly and was greatly enjoyed by those present.

St. Louis.—September 28, 1921, Engineers Club. Subject: "The Relation of the Institute and the Student Branch." Speaker: Professor W. L. Upson, of Washington University. The meeting was concluded with motion pictures of Grand Canyon giving some idea of the proposed enormous water power possibilities in this district. Attendance 40.

October 26, 1921, Century Electric Company. The entire membership of the Associated Engineering Societies was invited to be the guests of the St. Louis Section of the A. I. E. E. Subject: "The Automatic Start Polyphase Induction Motor." Speaker: Mr. J. L. Hamilton, Chief Engineer, Century Electric Company. Attendance 210.

San Francisco.—September 23, 1921, Engineers' Club. Subjects: "Rates of Electricity in Mining Districts" by Mr. R. E. Fisher; "How Operation About a Mine or Metallurgical Plant Can be Scheduled to Fit a Power Contract" by Mr. B. B. Beckett; "Application of Electricity to Mining and Milling at the Alaska Gastineau Plant" by Mr. B. L. Phane; "Prevention of Accidents in Mining Operation" by Mr. R. L. Eltringham. Attendance 80.

Schenectady.—October 13, 1921, Edison Club Hall. Special joint meeting of Schenectady Section A. I. E. E., Schenectady Board of Trade, Eastern New York Section A. S. M. E. and Society of Engineers of Eastern New York. Subject: "Pressing Industrial Problems." Speaker: Mr. Magnus W. Alexander. Managing Director of the National Industrial Conference Board. Attendance 175.

October 21, 1921, Edison Club Hall. Subject: "Third Harmonics in Transformers." Speaker: Mr. G. Faccioli, of the Pittsfield Works, General Electric Company. The speaker described the distortions in the electromotive force and current waves that may occur in case of certain types of connections in single-phase transformers, when connected in a three-phase bank, and in the case of three-phase transformers of shell-type construction. He described how these distortions were the result of third and higher harmonics, but principally third harmonics. These harmonics are the natural result of the magnetic properties of iron. Mr. Faccioli showed to what extent it is possible for the potential to rise as a result of this third har-

monic phenomena; and how these excessive potential conditions are often aggravated by connecting the transformer bank to a high-tension transmission line. In closing, the speaker explained how these excessive potentials resulting from third harmonics, can be converted into harmless third harmonic Currents by the simple expedient of using such types of transformer connections or so connecting the neutrals of generators and transformers, or the neutral of one bank of transformers with that or another suitable bank in such manner as will permit the flow of third harmonic current. Attendance 200.

Seattle.—October 18, 1921, Commercial Club Rooms, Tacoma, Wash. Subject: "The Economic Side of Engineering Plans." Speaker: Professor William A. Russell, of the University of Washington. The speaker said in part that the moment an engineer passes out of the cycle of his earliest work devoted to (a) questions of absolute cost, and (b) relative cost of projected construction, and enters the domain of planning work proper, embracing as this does the question of revenues, he is placed face to face with the economic problem of values, of utility, of human wants, needs and desires. During the last twenty years production has been rapidly catching up with the so-called recognized demand, and the attention of the industrial world is turning towards satisfaction of the latent demands of humanity; this fact being shown by the advent of industrial engineers, management engineers, etc. The planning engineer is turning more from questions of cost and profit to problems of eventual benefit to society as a whole. As isolated units many engineers are giving their efforts to problems of national economics, as witnessed by the acceptance of a cabinet post by Mr. Herbert Hoover. But collective activity on the part of the organized engineers of this country in "engineeringly" planning the economic future of humanity is still in its infancy about the only conspicuous instance being the report on causes of economic wastes prepared by the American Engineering Council. The systematic study of economic problems and their solution by engineering methods of approach must be recognized as a basic function of all engineering associations. Attendance 40.

Spokane.—October 28, 1921, Davenport Hotel. Subject: "Intake Works of the Spokane Upper Falls Station." Speaker: Mr. L. J. Pospisil. Attendance 18.

Toronto.—October 14, 1921, Engineers' Club. Social Evening and Get-Together Meeting. The meeting was opened by an address on the Aims and Activities of the Institute by Mr. W. F. Wright, followed by a brief talk on the privileges of membership by Mr. W. Amos. The program consisted in orchestral and vocal selections interspersed with instrumental solos, together with talks on current topics by members of the Section. Light refreshments were served, and an excellent opportunity given for old and new members to become better acquainted. Attendance 80.

October 28, 1921, Chemistry and Mining Building, University of Toronto. Subject: "Manufacture of Incandescent Lamps." Speaker: Mr. Brownlee, of the Sunbeam Lamp Co. The speaker stated that owing to the breadth of the subject it would be necessary that he confine his attention solely to one type, the vacuum lamp. He first called attention to the very low efficiency of even the best lamp, and stated that as every possible element has been tried for filament material, it would appear that much increased efficiency in light production can only be attained by the development of some new principle. He then gave a very instructive illustrated talk on the assembly, basing and factory tests of lamps, with particular attention to the requisites and development of filaments, tracing the development through the platinum, carbon, treated carbon, matalized filament, osmium, and tantalum to the present day tungsten filament. Details were given of the production of tungsten from the raw ore to the drawn wire, and interesting data of filament design were presented. The speaker explained the principle of the so-called "vacuum getters" whose object is to render transparent the tungsten compounds which are deposited in the interior of the bulb. Explanation was also given of the requirements of the lead-in wires, showing how they have developed from pure platinum to the present inexpensive and very efficient seals. Mr. Zay Jefferies, of Cleveland, also spoke on the matallurgical properties of the tungsten. Attendance 77.

Utah.—October 28, 1921, Commercial Club. Subject: "The Electrification of Trunk Line Railways." Speaker: Dr. J. F. Merrill, Dean of the College of Engineering of the University of Utah. Dr. Merrill reviewed the development of railway electrification up to the present time and presented valuable data as to the economies that were possible by the use of electrification. Mr. C. P. Kahler, of the Oregon Short Line R. R., followed Dr. Merrill with a paper on "Characteristics of Steam and Electric Railways." Mr. Kahler presented valuable data as to the costs of operating and maintaining steam locomotives and analyzed the questions to show under what conditions electrification is feasible and economical. Following the papers the moving picture "King of the Rails" was shown. Refreshments were served. Attendance 50.

Vancouver.—October 7, 1921, Board of Trade Auditorium. Subject: "Electric Pumping for Irrigation, Reclamation and Drainage." Speaker: Mr. G. R. Alexander, of the Byron Jackson Iron Works, San Francisco. The talk was illustrated with forty-five excellent slides. Attendance 37.

November 4, 1921, Board of Trade Auditorium. Subject: "Modern Street Lighting." Speaker: Mr. F. W. MacNeill, Sales Engineer of the Canadian General Electric Company. The talk was illustrated with fifty-one slides. Attendance 37.

Washington.—October 11, 1921, Cosmos Club Hall. Subject: "The Principles of the Radio Direction Finder." Speaker: Mr. L. E. Whittemore, Radio Section, Bureau of Standards. The subject was illustrated with lantern slides and with apparatus showing the application to Marine Navigation. Mr. D. H. Shellcross, Bureau of Engineering and Director of Naval Communications, spoke on "Naval Radio Compasses;" and Major L. B. Beudev, Signal Corps, U. S. A., on "Radio in the Army." Mr. A. Crossley, Expert Radio Aide in Charge of Research Section, Radio Division, Bureau of Engineering, Navy Department, spoke on "Radio Developments." Attendance 140.

Worcester.—October 20, 1921, E. E. Building, Worcester Polytechnic Institute. Subject: "Modern Illumination and Its Application." Speaker: Mr. James Ketch, of the National Lamp Works, Cleveland. Attendance 60.

PAST BRANCH MEETINGS

University of Arkansas.—October 14, 1921. Election of officers as follows: Chairman M. X. Ware; Vice-Chairman, J. A. Thompson; Secretary, B. R. Askew; Treasurer, L. G. Huggins. Professor W. B. Stelzner discussed Student enrolment in the A. I. E. E., and the scope of action for the Branch during the coming year. Attendance 14.

October 18, 1921. Subjects: "The Field of Engineering, dealing with its Past History and Present Possibilities" by Dean W. N. Gladson; "Electric Propulsion of Battleships as Discussed in the A. I. E. E. Journal" by J. C. Albritton. Attendance 19.

November 1, 1921. Subjects: "Outstanding Characteristics of the Modern Power Plant" by Gale Huggins; "Current Superheater Practise as Discussed in the A. S. M. E. Journal" by L. M. Jory. Attendance 16.

Armour Institute of Technology.—October 27, 1921. Subjects: "Wireless Aboard Ship" by A. R. Mehroff; "Railroad Signaling" by R. S. Kenrick. Attendance 53.

Brooklyn Polytechnic Institute.—October 14, 1921. Election of officers as follows: Chairman, Henry Ladner; Vice-

Chairman, A. E. Shaw; Secretary, O. Engstrom; Treasurer, Marvin Leibowitz. Attendance 30.

November 4, 1921. Subject: "Electrochemistry." Speaker: Dr. Caldwell, Department of Chemistry, Brooklyn Polytechnic Institute. Attendance 77.

Bucknell University.—November 7, 1921. Subject: "Manufacture of Tungsten Bulbs." Speaker: Professor Hall. Attendance 36.

University of California.—October 12, 1921. Subject: "Hydro-Electric Design and Construction." Speaker: Mr. W. P. L'Hommidieu, of the San Francisco Office of the Westinghouse Elec. & Mfg. Co. Attendance 44.

October 26, 1921. Subject: "Development of the Caribou Power Plants of the Great Western Power Company." Speaker: Mr. J. A. Koontz, Jr., of the Great Western Power Company, San Francisco. The talk was accompanied by a showing of two reels of films of the development. Attendance 42.

Carnegie Institute of Technology.—November 3, 1921. Subject "Electrification of Railroads and the Relative Advantages of Alternating-Current and Direct-Current on Railroads." Speaker: Mr. N. W. Storer, of the Westinghouse Electric & Manufacturing Company. Attendance 63.

Case School of Applied Science.— October 11, 1921. Following dinner at the Case Club, Mr. C. G. Maxwell gave a highly instructive talk on "The Utilities Industry—Its Economic Side." Attendance 46.

University of Cincinnati.—September 26, 1921. Subject: "The Working Tools of an Engineer, viz., English, Mathematics and Common Sense." Speaker: Professor A. M. Wilson. Attendance 85. (Section I.)

October 10, 1921. Subject: "The Working Tools of an Engineer, viz., English, Mathematics and Common Sense." Speaker: Professor A. M. Wilson. Attendance 72. (Section II.)

October 17, 1921. Subject: "Psychology and Personality." Speaker: Professor B. B. Breese. Attendance 80.

October 24, 1921. Subject: "The New Tesla Outfit Constructed at the University of Cincinnati." Speaker: Mr. A. B. Smedley. Attendance 82.

Clarkson College.—October 4, 1921. Election of officers as follows: Chairman, Richard L. Conboy; Secretary, Francis H. Fults; Treasurer, Clarence E. Fuites. Subject: "Some Phases of Electrical Railway Engineering." Speaker: Professor A. R. Powers. Attendance 23.

October 18, 1921. Lantern slide lecture on "The Advancement of the Electrical Industry." Films of the General Electric plants at Schenectady, N. Y., and Pittsfield, Mass., were also shown. Attendance 26.

November 1, 1921. The following General Electric Company films were shown: "Revelations of X-Ray" and "Production of Lamp Cord." Mr. Stebbins of the Western Electric Company, gave a short talk on the educational service of that Company. Attendance 22.

University of Colorado.—October 27, 1921. Mr. F. B. Doolittle gave a report on the A. I. E. E. Convention at Salt Lake City. Mr. R. E. Hieronymus gave an account of the theory and operation of the telegraphone. Attendance 35.

Iowa State College.—October 26, 1921. Regular quarterly smoker and get-acquainted meeting. Talks by the following: Professor F. A. Fish on "Essentials for Success"; Professor E. R. McKee on "College Activities"; Professor E. C. Kurtz on "The Field of Electrical Engineering"; Mr. L. D. Martin, Senior Electrical Engineering Student, on "Ames Engineers Away from Ames;" T. O. Millard, Senior Electrical Engineering Student, gave several impromptu stories from an unceasing supply; and Professor R. O. Joslyn on "Ames as an Engineering College." Music was furnished by Metcalf's orchestra. Refreshments were served. Attendance 124.

University of Kansas.—October 20, 1921. Subjects: The Keokuk Plant" by W. Anderson; "The Two-Cycle Multimotor" by C. W. Campbell; "Retracing Compass Lines in the East" by Professor Ockerblad. Attendance 56.

November 3, 1921. Subjects: "Circuit Breakers" by Mr. Schlagg; and "Electric Welding" by Mr. Covey. Further discussion of both subjects by Professor Shaad. Attendance 51.

Lehigh University.—October 13, 1921. Subjects: "Electrification of the Chicago, Milwaukee & St. Paul Railroad" by Mr. J. D. Aldrich; "Modern Developments in Electric Machinery" (illustrated) by Mr. H. G. Harvey. Attendance 41.

Lewis Institute.—November 2, 1921. Election of officers as follows: Chairman, E. Millison; Secretary-Treasurer, E. R. Lindberg. Attendance 14.

University of Maine.—October 19, 1921. Election of officers as follows: Chairman, Foster Blake; Vice-President, H. S. Dennison; Secretary, C. Roger Lappin; Treasurer, Perry Shean.

October 25, 1921. Subject: "Modern Power Plant Practise." Speaker: Mr. H. W. Smith, of the Westinghouse Electric & & Mfg. Co. Attendance 80.

Michigan Agricultural College.—October 25, 1921. Talks by the following: Professor Cory on "The Qualities to be Looked for in an Engineer"; Professor Foltz on "How to Improve Oneself"; Mr. Rayner, a senior, gave a few interesting demonstrations of high-frequency current; Mr. Kinney, of the Electrical Department, demonstrated the theory and use of the transformer; Professor Sawyer spoke on "Selecting One's Life Work." Refreshments were served. Attendance 45.

University of Michigan.—October 26, 1921. Subject: "From Legs to Motored Wheels" (illustrated). Speaker: Mr. Arthur E. Leet of the Mercury Manufacturing Company. Attendance 78.

University of Minnesota.—October 19, 1921. Subjects: "Aims and Purposes of A. I. E. E." by Mr. A. W. Wilson; "Prospects for the Graduating Engineer" by Mr. H. S. Langland; talks by Messrs. J. E. Magnusson, J. E. Sorenson and J. M. Downie; and violin solo by Mr. O. F. Heidelberger. One reel of moving pictures was also shown. Attendance 43.

University of Nebraska.—October 19, 1921. Short talks were given by Messrs. Lloyd Shildneck, Lewis S. Grandy and Merle Rainey concerning their summer's work with the Commonwealth Edison Co. of Chicago. Mr. Albert P. Strom gave an illustrated talk on the hydroelectric plants of Sweden. Attendance 30.

University of North Carolina.—November 1, 1921. Subjects: "History and Purpose of University Branch A. I. E. E." by Professor P. H. Daggett; "Work before Us this Year" by Professor J. H. Mustard; "Advice to New Men" by Professor J. E. Lear. Attendance 70.

University of Notre Dame.—October 17, 1921. Subject: "Direct-Current Motor Starting and Control." Speaker: Mr. Dooling, instructor. Attendance 28.

November 7, 1921. Subjects: "College Education for Engineers" by J. Huether; "Standardization of Electrical Symbols" by Ray Black. Attendance 30.

Ohio State University.—October 27, 1921. Talks by seniors and also by Professor Caldwell. Refreshments were served. Attendance 50.

November 10, 1921. Subject: "The Engineering of Men." Speaker: Mr. Willard Beahan, of the New York Central Lines. Attendance 300.

Oklahoma Agricultural and Mechanical College.—October 17, 1921. Professor Miller explained the purposes and benefits of the A. I. E. E. to new men. Mr. Bullen explained briefly the General Electric test at Schenectady, N. Y. Attendance 18.

University of Oklahoma.—October 20, 1921. Subjects: "Value of Illumination to Business Advertisement" by A. H. Schlechter; "Growth of Radio in the Next Few Years" by M. T. Prescott; "Practical Experience and Theory" by I. B. Watkins. Attendance 38.

Oregon Agricultural College.—October 19, 1921. Subject: "Some of the Aspects of the Commercial Field of Electrical Engineering." Speaker: Mr. William M. Hamilton, Manager of the Valley Division of the P. R. L. & P. Attendance 80.

Rensselaer Polytechnic Institute.—October 18, 1921. Remarks were made by several of the faculty on the history of the A. I. E. E., the local branch, advantages of Student enrolment and the like. Attendance 110.

October 27, 1921. Mr. Albert A. Northrop of Stone and Webster, Inc., described in a lecture well illustrated by colored slides and motion pictures, the Caribou 60,000-kw. hydroelectric development recently completed by Stone and Webster for the Great Northern Power Company. Attendance 325.

Rose Polytechnic Institute.—September 20, 1921. Get-together meeting with talk by Professor Knipmeyer on student activities. Attendance 49.

September 27, 1921. Motion pictures news films showing tests made by the General Electric Company with electrical pressures of a million volts. Attendance 49.

October 18, 1921. A report on the mechanical and electrical equipment of the T. H. I. and E. Power House. Mr. Pittman reported on the mechanical and Mr. Offut on the electrical equipment. Attendance 26.

October 26, 1921. Inspection trip to the T. H. I. and E. Power Plant. Attendance 32.

November 1, 1921. Informal talk by Professor Knipmeyer on mercury arc rectifiers in arc lighting circuits. Attendance 14.

November 8, 1921. Informal talk by Dr. Woodworth, President of Rose Polytechnic Institute, on the proper attitude of the engineering graduate in seeking employment. Attendance 22.

University of Southern California.—October 19, 1921. Subject: "Railways—Past, Present and Future." Speaker: Mr. L. S. Peterman, of the Southern California Edison Company. The talk was illustrated with slides. Attendance 37.

Stanford University.—October 6, 1921. Election of officers as follows: Chairman, Hugo Becker; Vice-Chairman, Charles Ellis; Secretary, Vernon Marquis. Attendance 25.

Syracuse University.—October 1, 1921. Election of officers as follows: Chairman, Eugene Ryan; Vice-Chairman, Robert J. Swackhomer; Secretary A. Percival Fugill. Attendance 9.

October 10, 1921. Subject: "Electric Ship Propulsion." Speaker: Mr. Minor P. Avery. Attendance 10.

October 13, 1921. Subject: "Electricity and the Automobile" Speaker: Mr. Ralph H. Baker. Attendance 7.

October 27, 1921. Subject: "Niagara Power Company, Power Plants at Niagara and Colfax Power Plant at Pittsburgh." Speaker: Mr. A. Percival Fugill. Attendance 9.

A. & M. College of Texas.—October 4, 1921. Subjects: "The Junior Electrical Engineering Student's Inspection Trip" by Mr. H. E. Schmidt; "What Leading Engineers Think of College Graduates" by Mr. R. B. Steele. Brief talks were made by Messrs. F. C. Bolton and O. B. Wootsen. Attendance 50.

October 18, 1921. Subjects: "Application of Electrical Power in Removing Coal from Mines" (taken from A. I. E. E. JOURNAL), by J. J. Myly; "A Short Discourse on the Law of Relativity" by C. R. Clark; "Show-Window Lighting" by J. J. Lang. Attendance 54.

Virginia Polytechnic Institute.—November 2, 1921. Election of officers as follows: Chairman, D. P. Minichan; Secretary-Treasurer, T. F. Cofer. Attendance 26.

University of Washington.—November 1, 1921. Subject: "Electric Heating in Tacoma." Speaker: Professor E. A. Loew. Attendance 31.

West Virginia University.—October 20, 1921. Subjects: "'Discussion of Engineering Society" by H. S. Shinn; "Multiplex Telegraphy and Telephony" by W. D. Stump; "The Automatic Reclosing Circuit Breaker" by C. M. Hill; "Electrostatic Dust Precipitator" by J. L. Hark; "The Limitation of the Stop Watch" by A. E. Lapie; "Iron Commutators" by F. Donnelly; "The Development of Magnetic Materials" by H. Chandler. Attendance 23.

November 2, 1921. Subjects: "Electric Ranges" by R. K. Park; "Report of American Railway Association" Porter; "Electropercussive Welding" Ernest; "Importance of Electricity on Automobiles" Mendelsohn; "Combatting Fires in Transformers and Oil Switches" Moffett; "Business Outlook for Electrical Men" Hutson; "Problems Involving Illumination of Signs and Signboards" J. R. Richards. Attendance 25.

ADDRESSES WANTED

A list of members whose mail has been returned by the Postal Authorities is given below, together with the addresses as they now appear on the Institute records. Any member knowing the present address of any of these members is requested to communicate with the Secretary at 33 West 39th Street.

1.—John A. Dickie, Hotel Washburn, Waukegan, Ill.
2.—F. G. Ding, 1124 Ross Ave., Wilkinsburg, Pa.
3.—R. L. Ehmann, 4636 North St. Louis Ave., Chicago, Ill.
4.—W. J. Epps, Rua Dom Geraldo 80, Rio de Janeiro, Brazil S. A.
5.—G. Foung, Kay Sang & Co., 843 Clay St., San Francisco, Calif.
6.—H. L. Francis, F. C. Central Dominicano, Puerto Plata, Dominicano, Rep.
7.—Geo. P. Hoisington, 551 Aldine Ave., Chicago, Ill.
8.—T. J. Hodge, 612 West 137th St., New York, N. Y.
9.—Hugo Wm. Jacobson, 1402 East 63rd St., Chicago, Ill.
10.—Scott J. Kennedy, 632 East 17th St., Oakland, Calif.
11.—Howard W. Key, Russell Mfg. Co., 60 So. Forsyth St., Atlanta, Ga.
12.—Louis Kusner, Westinghouse Elec. Mfg. Co., Swdb. Engg. Dept. K-90, East Pittsburgh, Pa.
13.—G. H. Lindsey, Rosemere Apts., 2225 West 14th St., Los Angeles, Calif.
14.—Chas. C. Long, 1109 Arizona Ave., El Paso, Texas.
15.—George C. McCabe, 137 West 86th St., New York, N. Y.
16.—Harry P. Meyer, 327 East 61st St., Los Angeles, Calif.
17.—E. L. Neill, Box 401, Palo Alto, Calif.
18.—Chas. Schindler, Great Western Power Co., Crockett, Cal.
19.—E. V. Stoute, 1946 Mosher St., Baltimore, Md.
20.—R. H. Terry, 217 West Mifflin St., Marchson, Wis.
21.—Frank N. Tucker, 551 East 40th St., Chicago, Ill.
22.—T. S. Yang, Yonkers Y. M. C. A., Yonkers, N. Y.

EMPLOYMENT SERVICE BULLETIN

OPPORTUNITIES.—Desirable opportunities for service from responsible sources are announced in this Bulletin, and no charge therefor is made.

MEN AVAILABLE.—Under this heading brief announcements (not more than fifty words) will be published without charge to the members. Announcements will not be repeated except upon request received after a period of three months, during which period names and records will remain in the active files.

NOTE.—Notices for the JOURNAL **should be addressed to EMPLOYMENT SERVICE, 33 West 39th Street, New York, N. Y.,** *the employment clearing house of the Societies constituting the Federated American Engineering Societies, and* **not** *to the A. I. E. E.*

Notices for the JOURNAL are not acknowledged by personal letter, but if received prior to the 16th of the month will appear in the issue of the following month.

All replies to either "Opportunities" or "Services Available" should be addressed to the key number indicated in each case **and forwarded to EMPLOYMENT SERVICE, as above.**

Replies received by the bureau after the position to which they refer has been filled will not be forwarded, and will be held by the bureau for one month only.

Information regarding the notices published is on file in the offices of the member societies of the Federated American Engineering Societies.

POSITIONS OPEN

ENGINEER experienced in operating a fleet of motor trucks. Special experience in the cost of operation, handling of packages, etc. Application by letter. Location, New York City. X-1159.

YOUNG MAN with thorough technical training in electricity as applied to manufacture of heating units and motors. Desire a man capable of determining faults in design and manufacture of electric melting pot used on line casting machine. Position expected to expand to extent that man will be required to visit customer's plants and determine faults in pots that are not correctly operating. Also chance for man to make improvements in design or create an entirely new pot, if desirable. It is expected that work will later develop so that he will have chance to inspect and supervise the general operation of motors used on machines. Need not have any practical experience along this immediate line, but must have sufficient technical knowledge to fit him for above duties, a personality that would warrant sending him into customer's plant, and the judgment and initiative necessary to carry out the above outline. Application by letter giving full qualifications, including age, nationality, training and salary desired. Location New York. X-1234.

ENERGETIC ELECTRICAL MAN with executive, estimating and new business abilities, to take complete management of a going electrical contracting and repair business, may invest if desired. Application by letter. Location Brooklyn, N. Y. X-1241.

GRADUATE ELECTRICAL ENGINEER for research laboratory. Young man of pleasing personality. Must possess an analytical or research attitude and should also be able to present new ideas and developments in lighting to others. Work is entirely along the lines of utilization of light. Application by letter. Location, Cleveland, O. X-1265

SUPERINTENDENT for small municipal hydroelectric plant, town of about 2000 population, operating commercial and street lighting service; must have had experience in line construction work and be willing and able to assist with lineman and ground hand in maintenance and new work. Should understand generator and switchboard wiring, interior wiring, meters, etc., and be capable of taking charge of generating and distributing plant. Living in this town is comparatively inexpensive and this is good opportunity for man who desires to transport his family from city to the country. X-1291.

TRANSMISSION LINE SUPERINTENDENT. Applicant must be conversant with both theory and practise in transmission lines, 100,000-volt, three-phase, 50-cycle. Must be capable of taking entire charge of transmission system of approximately 400 miles of lines, must be familiar with both construction and operating work, and must be capable of handling native help. Reply stating age, experience, training and salary desired. Location India. X-1292.

ELECTRICAL ENGINEER capable of making electrical layouts, inteviewing clients and supervising outside installations. Application by letter only. Location, New York City. X-1325.

RECENT TECHNICAL GRADUATE IN ELECTRICAL ENGINEERING. Qualifications for this position are that applicant must have electrical engineering degree from technical school of highest standing and must have a personality suitable to fit into and grow with organization. Practical experience is not necessary as we prefer recent graduate who has not been out of school long enough to become rusty on alternating-current theory. Application by letter stating age education. Location, New York City. X-1326.

ASSISTANT PROFESSOR IN ELECTRICAL ENGINEERING, for the second term of the school year. Work begins February 1st. Possibilities of continued appointment. Prerequisites—teaching and practical experience, character, personality and executive ability. Location, New England. X-1328.

INSTRUCTOR IN ELECTRICAL ENGINEERING for the second term of the school year. Work begins February 1st. Possibilities of continued appointment. Prerequisites—teaching and practical experience, character, personality and executive ability. Location, New England. X-1329.

RECENT M. E. & E. E. for telephone station layout and inspection of telephone apparatus. Location, New York City. X-1334.

INSTRUCTOR in automobile and motor truck operation, automobile construction and repair, and farm machinery. Permanent, full time position. Actual experience in the operation and repair of automobiles, trucks, and tractors. Application by letter stating age, education and experience. Position with correspondence school. X-1336.

ASSISTANT IN ELECTRICAL ENGINEERING DESIGN. Should be technical college graduate and should preferably have some experience in electric design, manufacture and testing, but need not necessarily be finished designer. Work will include electric and magnetic design calculations for a wide variety of devices, both a-c. and d-c., and will bring the man into close contact with both the manufacturing and the laboratory departments of our organization. Position permanent if applicant proves satisfactory and will offer opportunities for advancement. Application by letter, stating age, education and experience. X-1338.

EDITOR WANTED for well established monthly publication devoted to the stationary power plant field. Covers steam and electric engineering, refrigeration and other allied engineering subjects. Further details can be secured by correspondence and applicants should indicate in their first letter their general qualifications for such a position. X-1350.

SALES ENGINEER for manufacturer of steel transmission poles and towers; must be well educated in electrical engineering, have working knowledge of steel construction; preferably man with experience in the sale of transmission towers. Give complete information as to education, experience, salary, trade experience, references. Also, if possible, send photograph. Postion has large possibilities for right man. X-1378.

SUPERINTENDENT OF POWER STATION. Must be a man who has had at least three years charge of natural gas and Diesel engine-driven generating sets, of approximately 500 h. p. Total capacity of plant, 3000 kw. High-tension system, 19,000 volts. Engines are Westinghouse; Snow; McIntosh-Seymour. Generators G. E. Modern full improved house provided, including light and heat. X-1379.

MEN AVAILABLE

EXPERIENCED ELECTRICIAN. Substation construction, operating and armature winding; two years technical training. Age 24, single. Will go anywhere. E-3065.

GRADUATE ELECTRICAL ENGINEER, age 25, married, desires position with chance for advancement. One and one-half years experience engineering department company manufacturing physio-therapy and X-ray equipment. Experience with ultra-violet apparatus such as used in water sterilization. Familiar with recent developments in actino-therapy. E-3066.

TECHNICAL GRADUATE, age 28, with six years experience, including engineering in distribution and operating department of public service company; tests, and construction, with manufacturing companies; wishes position with public utility company or with manufacturing concern. Location immaterial. Available immediately. E-3067.

HYDROELECTRIC SWITCHBOARD OPERATORS—TWO, with technical training. Desire positions with large power company. Will go anywhere. E-3068.

MECHANICAL AND ELECTRICAL ENGINEERING GRADUATE, class 1920, age 28. Desires position in electrical engineering field or as instructor in elementary electrical engineering, physics or mathematics or as laboratory instructor in electrical engineering or physics. No teaching experience. Experienced in designing and opera-

tion of oil refining machinery, hydroelectric designing and operation and commercial fields. Prefer Pacific Island, South America or China. Employed at present. E-3069.

INDUSTRIAL ENGINEER, now Electrical Engineer of works with 1200 motors, 130 cranes, power plant, etc. Age 34, Mem. A. S. M. E., Mem. A. I. E. E., etc. $6000. E-3070.

CHIEF MINE AND MILL ELECTRICIAN, married, 25, hard worker with initiative and pep. Six years hard practical experience, two years college work, technical education mostly self attained. Capable rewinding, reconnecting motors, experienced on both alternating-current and direct current. Experience covers most up-to-the-minute electrical practises about mine and mill. Good references, Assoc. A. I. E. E. Go anywhere. Present contract expires January 1, 1922. E-3071.

TURBINE ENGINEER—M. I. T., 1912; married, 36 years of age. Nine years experience in research and technical design of steam turbines; one year on design and construction of steam electric power plants. Wants a position of a research or consulting engineer with a progressive manufacturer or public utility concern or with a concern of consulting engineers. E-3072.

GRADUATE ENGINEER (E. E.), age 31; experience, sales engineering, plant engineering, testing, distribution and transmission engineering, present work matter of confidential correspondence. Desires position in commercial or industrial engineering work (not traveling) or central station. Location, Middle West, New York or New England States. Associate A. I. E. E. E-3073.

ELECTRICAL MECHANICAL ENGINEER fourteen years experience, factory testing, engineering, commercial work, engineer and assistant superintendent of large hydrosteam power company, superintendent electric department railway electric light and power company, in electric engineering department of holding company. Age 36; married. Available immediately. Desires position as manager of electric utility. E-3074.

ELECTRICAL ENGINEER, Age 22. University of Michigan graduate. Member A. I. E. E. One year sales experience. Two years appraisal work. Desires position with company in foreign country. Location immaterial. Available after November 1st. E-3075.

ELECTRICAL AND MECHANICAL ENGINEER, age 43, open for engagement anywhere. Has over twenty-two years experience in power house construction, operation, and maintenance, also all kinds of railway work, substations etc. Low and high-tension work up to 100,000 volts. Has been in charge as superintendent for 9 years of 145,000-h. p. plant. E-3076.

EXECUTIVE ENGINEER, desires change in location. Eastern Canada or United States preferred. Proved ability along constructive and productive lines. E-3077.

TECHNICAL GRADUATE, age 27, single, 3 years experience with power company, 4 years with manufacturing concern, drafting, wiring diagramming, testing, etc. Desires position with growing concern, preferably in East but will go anywhere. E-3078.

TECHNICAL GRADUATE, with electrical and steam power plant experience and now employed as power superintendent desires change. Sales preferred. E-3079.

MECHANICAL AND POWER ENGINEER. Technical graduate, B. S. and M. E., age 30, eight years experience along broad lines, chemical, machine shop, metallurgy, sugar engineering, industrial and power plant practise, operation, design, layout, calculations, heating, distribution of steam, water, etc. Has business and executive ability. Desires responsible position. E-3080.

ELECTRICAL CONSTRUCTION ENGINEER AND SUPERINTENDENT. Age 32, technical graduate, 12 years experience on high tension pole and tower lines, substations, etc., construction and engineering. At present holding responsible position, but would like change to South, California, or foreign country. Can organize and handle men to an advantage. Member A. I. E. E. Present salary $300. Excellent references. E-3081.

YOUNG MAN, 20 years of age, desires position as laboratory assistant, or switchboard operator. Two years technical training, two years operating experience. E-3082.

ELECTRICAL ENGINEER, qualified for purchase, installation, and maintenance electromechanical equipment for large coal company. Best references present employers, whom I serve in above capacity. Under 30 but possessing genuine experience from apprentice to present position besides college education. If you want a cheap man don't waste your time or mine. E-3083.

TECHNICAL GRADUATE, INDUSTRIAL ELECTRICAL ENGINEERING, 12 years varied electrical experience in construction, operation and maintenance, four years G. E. test and office experience. Desires position as operating or maintenance engineer or assistant to electrical engineer in charge. Single, 35, minimum salary $1800. Available at once. E-3084.

SALES MANAGER, Electrical Engineer, age 40, desires position in charge of sales; central station and manufacturing experience. Excellen record. E-3085.

MANAGEMENT ENGINEER, well versed in finance, manufacture and construction, will be available about January 1st. Graduate Electrical Engineer. Experienced and capable executive. Age 30. Married. E-3086.

SELLING ENGINEER—EXECUTIVE, technical and university graduate; broad, practical, successful, business experience, notably sales. Affable, resourceful, personality. Straight thinking executive. Desires connection on selling end of well established concern where his opportunity for advancement is commensurate with results, initiative, and executive ability. Basis, salary and commission. Commercial and bank references. E-3087.

ELECTRICAL ENGINEER, recently connected with pumping machinery manufacturers as sales engineer, now available for position in sales, construction, or maintenance work. Married. Age 40. Eighteen years past experience in electrical and mechanical fields. Some designing, drafting, testing, inspection, contracting experience. Associate A. I. E. E. Master Electrician for City of N. Y. E-3088.

POWER ENGINEER OR SUPERINTENDENT, technical graduate, age 35. Member A. I. E. E. Experience covers management, operation and maintenance, steam and hydraulic plants both industrial and public utilities. Desires position where analytical and constructive ability leading to plant betterments is demanded. Middle Atlantic or Southern location preferred. Available early 1922. E-3089.

ENGINEER—EXECUTIVE. Assoc. A. I. E. E. Age 28, technical graduate 1915, experience test, design, installation, sales-engineer, d-c. and a-c. motors, control, switchboards, hoists. Thorough knowledge and experience of branch office management. Desires position as branch office manager or technical executive with reliable manufacturer. Available on short notice. Salary $3500. E-3090.

ELECTRICAL AND MECHANICAL ENGINEER, age 28, married, technical education, 7 years experience including: Inventory and appraisal of public utilities, construction, inspections and surveys. Desires position as assistant to comptroller in manufacturing concern or electrical and mechanical engineer. Assoc. A. I. E. E. Available January 1, 1922. E-3091.

SUPERINTENDENT OR SUPERVISOR for electrical instrument establishment. 14 years of practical experience in handling men. Familiar with up-to-date methods of production and designing of complicated apparatus. Assoc. A. I. E. E. Salary $3000. Available on short notice. E-3092.

I. C. S. GRADUATE. Naval radio experience, two years work in power station design, some business experience and quick to learn. Desires distribution work for public utility; prefer New England position. Age 22; single; Associate A. I. E. E. and Class B, N. E. L. A. Salary determined by responsibilities assumed. E-3093.

ELECTRICAL ENGINEER. Age 25; Assoc. A. I. E. E. Four years engineering experience in research and manufacturing. Desires connection with concern installing electric drives in ships. Available on moderate notice. E-3094.

GRADUATE ELECTRICAL ENGINEER. Age 32. Desires position with an industrial firm or railway, light and power company. Two years Westinghouse Elec. Co. Testing Department. Four years experience in construction, operation and maintenance work with an industrial and power company. Would like to get a permanent connection with opportunities for advancement. E-3095.

ELECTRICAL AND MECHANICAL ENGINEER. Cornell graduate, with several years experience in general engineering, desires permanent connection with industrial plant, engineering firm or exporter. E-3096.

ELECTRICAL ENGINEER. Age 36. Seven years experience with lighting and railway companies, in generating and distribution departments. Five years in consulting engineers office on investigations, report, plans and specifications for various engineering projects. Appraisals and statistical work for Commission cases. Desires position in engineering department of public utility company. E-3097.

INDUSTRIAL ENGINEER OR WORKS MANAGER, who is a journeyman machinist, technical graduate and is familiar with modern methods of management, desires suitable connection with manufacturing concern. Fifteen years experience. E-3098.

ELECTRICAL ENGINEER. University of Minnesota Graduate. Age 27, single. Completed a course as student engineer with Cutler Hammer Mfg. Co. Was head of experimental Laboratory with same company's New York works. Had considerable practical experience in the installation of automatic substation equipment. Was chief electrician in U. S. Navy. Desires a position in controller engineering or affiliated lines. E-3099.

YOUNG TECHNICAL GRADUATE. Two years G. E. motor test. Three years of power substation design layouts. Also competent to do electrical calculations pertaining to transmission line design. Age 23 years. Available at once. E-3100.

SALES MANAGER, at present occupying this position with perfect satisfaction to employer, desires a change. Graduate B. Sc. (McGill) electrical, 1903, additional 3 years shop apprenticeship course. Responsible factory executive 6 years, followed by 6 years sales, four of which as manager. Only position of responsibility considered. E-3101.

RESEARCH ASSISTANT. Age 27, desires position with a concern or private party requiring a man with broad training as an assistant and executive in applied scientific research. Full particulars as to ability and experience will be supplied upon request. E-3102.

TECHNICAL GRADUATE IN ELECTRICAL ENGINEERING. B. S., Case, 1921, Student A. I. E. E., age 24, unmarried, desires position in any corporation or power company as construction and electrical engineer or any other position leading up to same. Opportunity, not immediate salary, main consideration. Available immediately, locate anywhere. E-3103.

YOUNG MAN, 22 with one year electrical technical training and five years of practical experience including research, central station and manufacturing; for the past one and a half years inspector and tester of automatic electric apparatus; would like position offering permanent location where past experience together with ambition is desired. E-3104.

ELECTRICAL ENGINEER desires work along line of electric railways or mine locomotives B. S. and E. E. degrees. One year with Pathe Freres Phon. Co., Brooklyn, N. Y.; several months with Boston Elevated Rwy. Co.; one year in testing department, Western Elec. & Mfg. Co., E. Pittsburgh, Pa. Latin-American origin; would consider South America. Associate A. I. E. E. E-3105.

SUPERINTENDENT, age 35, married. Desires position as plant or executive engineer with manufacturing or pulp concerns. Life long experience and technical training. Steam and hydroelectric construction and maintenance. Eight years experience in industrial electrification, maintenance and operation. At present power engineer for large pulp company. Salary $350. Available February 20, 1922. Assoc. A. I. E. E. E-3106.

ELECTRICAL ENGINEER, six years experience industrial plant applications and electrical department management, including steam power plants, 25,000 h. p. load. Broad experience with chemical industries, centrifugal pumping and difficult maintenance. Desires responsible position with consulting engineer or company with large electrical interests. Age 29, married, Assoc. A. I. E. E. State University graduate. E-3107.

ELECTRICAL ENGINEER—Age 25, technical graduate, 18 months G. E. test, 2 years experience in design and construction of switchboards and automatic substation equipments. Prefer automatic station work in Rocky Mountain or Pacific Coast states. E-3108.

ELECTRICAL ENGINEER—1919 Graduate desires position with firm making or selling arc-welding equipment. Experience includes both theoretical and practical work on arc welding. Location, East, preferable. Single, age 26. E-3109.

UNIVERSITY GRADUATE—age 31, married, 5 years experience on Westinghouse test, trouble work and general service wants position with electric railway, public utility, or large industrial plant. Has had experience teaching. Location Middle West. E-3110.

YOUNG MAN—23, has good technical training and initiative. Electrical engineering degree 1921 wishes position with future where advancement depends on personal ability. Manufacturing or testing desired, but others considered. E-3111.

ELECTRICAL ENGINEER—age 24, graduate, June 1921, from University of Michigan wishes position with some Power Plant in Middle West. Have had general wiring and maintenance experience. Available immediately. E-3112.

MEMBERSHIP — Applications, Elections, Transfers, Etc.

ASSOCIATES ELECTED NOVEMBER 17, 1921

ARMSTRONG, ADNA H., Electrician, Lundin Electrical Co., Boston; res., 285 Centre St., Dorchester, Mass.

BARNES, LYNN GARNSEY, Student Engineer, General Electric Co., Schenectady; res., 29 New Scotland Ave., Albany, N. Y.

BARRETT, ARTHUR CARPENTER, Combination Man, Mountain States Tel. & Tel. Company, Las Cruces, New Mexico.

BARRON, FREDERICK H., Draftsman, Adirondack Power & Light Corp., Amsterdam; res., 203 Huston St., Scotia, N. Y.

BASKIN, JOHN PIERCE, Draftsman, Georgia Railway & Power Co., 462 Electric & Gas Building, Atlanta, Ga.

CAINE, JACK F., Managing Director, English Electric Co., Ltd., 48 Milton St., London; res., Hurstleigh, Pinner, England.

D'ANDREA, MICHAEL EDWARD, Lakeside Drive, Rockville Centre, N. Y.

DOHL, ALFRED PHILLIP, Supervisor & Estimator, Electrical Construction, E. A. Koeneman Electric Co.; res., 1228 State St., East St. Louis, Ill.

EAMAN, THOMAS M., Sales Engineer, Fairbanks, Morse & Co., 594 Whitehall St., Atlanta, Ga.

ECKLES, FAYETTE BLAINE, Head of Testing Dept., Independent Electric Machinery Company; res., 1637 Chelsea Ave., Kansas City, Mo.

ELZNIC, FELIX F., Sales Manager, Charles Cory & Son, Inc., 183-187 Varick St., New York, N. Y.

FOSSATTI, P. G., Operating Engineer, Power Plant, International Paper Co., Jay, Maine.

GLASS, PAUL WINSOR, Engineer, American Tel. & Tel. Company, 195 Broadway, New York, N. Y.

GRAINGER, WILLIAM WALLACE, Robert A. Johnston Co., Milwaukee, Wis.

HAMILTON, JOHN, Power Station Supt., Hora Hora Power Station, via Tirau, Waikato, N. Z.

HARVEY, FRANK R., Chief Engineer, Taihape Borough Council Power Station, Elec. Dept., Taihape, N. I., N. Z.

HAYAKAWA, TOMINASA, Electrical Engineer, The Iwabuchi Electrical Engineering Co.; res., No. 12, 4 Chome, Iigura, Azabu-ku, Tokyo, Japan.

HIGUCHI, NAGAO, Engineer Officer, Imperial Japanese Navy; res., 605 W. 111th Street, New York, N. Y.

HOLLADAY, COLLIS HUNTINGTON, Engineer, Southern California Edison Co., 6th Floor Edison Bldg., 3rd & Broadway, Los Angeles, Cal.

HOXIE, HARVEY H., Sales Engineer, Ohio Brass Company, 907 Hobart Bldg., San Francisco, Cal.

HOYLE, BERNARD CLIFTON, Electrical Tester, General Electric Co.; res., 44 Mall St., Lynn, Mass.

HUMPHRIES, FRANKLIN R., Supervisor, Underground Dept., Philadelphia Electric Company, Philadelphia, Pa.

JOHNSON, MARTIN ARTHUR, Chief Electrician, Morris & Company, 5507 King Hill Ave., St. Joseph, Mo.

KERR, WILLIAM W., Electrical Engineer, Scottish Boiler & General Insurance Co., Ltd., Glasgow, Scotland.

KLAPHOLZ, MAURICE, Asst. to Head of Standardization Section, Engineering Dept., Edison Lamp Works, General Electric Co., Harrison; res., 454 S. Orange Ave., Newark, N. J.

LANSFORD, WILLIS R., Secretary, John Collins Co.; res., 3607 15th St., N. W., Washington, D. C.

MALKIN, LOUIS, 155 Newport Ave., Brooklyn, N. Y.

MARASIGAN, VICENTE, Electrical Engineer, Public Utility Commission; res., 441 Tennessee, Malate, Manila, P. I.

MASON, CARL D., Electrical Engineer, Argentine Light & Power Co., Argentine, Mich.

MATZ, CHARLES, Draughtsman, Northern Indiana Gas & Electric Co., 571 Hohman St., Hammond, Ind.

*McGINTY, ERNEST A., Engineer, Dept. of Electric Operation & Construction, Pacific Gas & Electric Co., San Francisco; res., 2506 Keith Ave., Berkeley, Cal.

NEVINS, ENNIS, Chief Engineer, City Water Works; res., 1141 E. Nevada St., El Paso, Texas.

NEWCOMB, HARRY FARRELL, Technical Employee, American Tel. & Tel. Company; res., 87 W. Industry St., Pittsburgh, Pa.

ORME, BASIL S., Chief Electrical Inspector, Insulation, Winding & Transformer Dept., Metropolitan-Vickers Electric Co., Trafford Park, Manchester, Eng.

QUIGLEY, DON L., Wire Chief, Central Union Telephone Company; res., 108 S. State St., Champaign, Ill.

RATHGEB, CHARLES CASPER, Superintendent of Construction, L. K. Comstock & Co., 21 E. 40th St., New York, N. Y.; Three Rivers, Que.

ROEWE, GEORGE J., Electrical Engineer, Ocean Accident & Guarantee Corp., 114 5th Ave., New York, N. Y.

SCOP, LEV, Works Manager, Messrs. John Robertson, Ltd., 79 May St., Belfast, Ireland.

SCOTT, WILLIAM, Electrical Engineer, Gore Borough Council, Power House, Gore, N. Z.

SCRIBNER, ELMER BENJAMIN, Chief Cable Tester, New York Edison Co., New York; Islip, N. Y.

SERY, RALPH JOSEPH, Superintendent of Maintenance, United Telephone Co.; res., 111 S. Green St., Monroe, Wis.

SHEA, THOMAS F., Technical Employee, American Tel. & Tel. Company; res., 7250 Kelly St., Pittsburgh, Pa.

*SILENT, HAROLD C., D. & R. Dept., American Tel. & Tel. Company, 195 Broadway, New York; res., 28 Hawthorn St., Brooklyn, N. Y.

SMITH, E. A., Superintendent of Construction & Assistant Chief Engineer, International Mercantile Marine Co., No. 1 Broadway; res., 596 Columbus Ave., New York, N. Y.

STEVENS, GEORGE C., Electrical Engineer, Caixa do Correio 205, Rio de Janeiro, Brazil, S. A.

STOWERS, ADDISON C., Technical Employee, American Tel. & Tel. Company; res., 7324 Kelley St., Pittsburgh, Pa.

TALLEY, W. E., Chief Electrician, Crescent Insulated Wire & Cable Co.; res., 1847 Greenwood Ave., Trenton, N. J.

TAYLOR, ORSON H., Electrical Superintendent The A. Bentley & Sons Company, 201-241 Belmont Ave., Toledo, Ohio.

THOMAS, GEORGE D., Chief Electrician, Nawn Contracting Company, Gilboa, N. Y.

TODD, ROBERT W., Engineer in Charge, Extra High Tension Switching Apparatus Development, Metropolitan-Vickers Electric Co., Ltd., Trafford Park, Manchester, Eng.

TOWNE, ROGER PERKINS, Inspector, Western Union Telegraph Company, 175 Congress St., Boston; res., 80 Milk St., Westboro, Mass.

WHITESELL, FRANK "E". LLOYD, New England Representative, Railway & Industrial Engineering Co., 136 Federal St., Boston, Mass.

Total 52.

*Former enrolled students.

ASSOCIATES REELECTED NOVEMBER 17, 1921

BURNS, THOMAS STEPHEN, Vice President & Treasurer, Acme Transport Company, Inc., 15-25 Whitehall St., New York; 749 Gotham St., Watertown, N. Y.

JEFFERY, RICHARD T., Asst. Engineer, Hydro-Electric Power Commission of Ontario; res., 8 Lonsdale Apts., Avenue Road, Toronto, Ont.

JOHNSTON, J. J. HUNTER, Mains Superintendent, Glasgow Corporation Tramways; res., Oakfield, Lenzie, near Glasgow, Scotland

MORPHET, FRANK K., Barnett Coal Company, Blairville, Pa.
PESTEL, ARTHUR, Designing Engineer, 557 W. 124th St., New York, N. Y.
SOARES, EUSTACE CHARLES, Electrical Engineer, Ophuls, Hill & McCreery, 112 W. 42nd St., New York, N. Y.

MEMBER REELECTED NOVEMBER 17, 1921

WOOD, FRANKLIN PORTER, Electrical Engineer, Woolfenden, Wood & Weber, 1109 Broadway, Denver, Colo.

MEMBERS ELECTED NOVEMBER 17, 1921

GRABE, CLARENCE G., Electrical Engineer, with Howard N. Eavenson & Associates, 1302 Union Arcade Bldg., Pittsburgh, Pa.
WEDMORE, EDMUND B., Director & Secretary, The British Electrical & Allied Industries Research Association, Westminster, London; res., 1 Sneath Ave., Golders Green, London, N. W., 11, Eng.

RECOMMENDED FOR TRANSFER

The Board of Examiners, at its meeting held November 14, 1921, recommended the following members of the Institute for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the Secretary.

To Grade of Fellow

HILL, HALBERT P., Vice-President & General Manager, Ophuls, Hill & McCreery Inc., New York.
McCONAHEY, WILLIAM M., Manager, Transformer Engineering Dept., Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa.

To Grade of Member

BALLARD, FREDERICK W., Senior Member, F. W. Ballard & Co., Cleveland, O.
JACOBUS, ROBERT F., Partner, Francisco & Jacobus, New York, N. Y.
KISHLAR, LAMAR M., Electrical Engineer, Wagner Electric Mfg. Co., St. Louis, Mo.
MACNEILL, FRANCIS W., Sales Engineer, Canadian General Electric Co., Ltd., Vancouver, B. C.
MOON, FLOYD L., Electrical Engineer, Motor Engineering Dept., Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa.
SEAMAN, EDWIN H., Chief Engineer, Johnson & Higgins, New York, N. Y.

APPLICATIONS FOR ELECTION

Applications have been received by the Secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a higher grade than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the Secretary before December 31, 1921.

Allen, Harry, Detroit, Mich.
Applegate, Lindsay M., Portland, Ore.
Ardiff, Robert J., Indianapolis, Ind.
Atherton, Alfred L., (Member), E. Pittsburgh, Pa.
Ball, Clarence E., Spokane, Wash.
Bassett, Clark L., Detroit, Mich.
Bealey, Walter DeV., Portland, Ore.
Bellamy, John I. S., Chicago, Ill.
Blackwell, William T., New York, N. Y.
Bliss, William J., Steubenville, Ohio
Brown, John J., Philadelphia, Pa.
Bruno, William A., New York, N. Y.
Burgess, Bert I., Peterboro, Ont.
Burkhalter, Rudolph, (Member), Trenton, N. J.
Canning, Dow V., Peterboro, Ont.
Cantrell, Willis R., Plainfield, N. J.
Card, Read H., Denmark, S. C.
Carmean, James H., Kansas City, Mo.

STUDENTS ENROLLED NOVEMBER 17, 1921

13686 Merkl, Frank M., University of Alabama.
13687 Kuder, Bernard, Johns Hopkins Univ.
13688 Peters, Ralph H., Kansas State Agri. Coll.
13689 Mark, Isaac, Jr., Mass. Institute of Tech.

13690 Kost, Herbert G., Carnegie Inst. of Tech.
13691 Liebeck, George S., Worcester Poly. Inst.
13692 Nelson, Earl L., University of Illinois
13693 Cadaval, Edwards G., University of Ill.
13694 Howard, John C., University of Illinois
13695 Mason, David H., University of Illinois
13696 Davis, Waldo E., University of Illinois
13697 Niemann, Wilmont E., University of Ill.
13698 Ralph, Lindley J., University of Illinois
13699 Beechler, Arthur K., University of Illinois
13700 Behrens, William J., University of Illinois
13701 Cheaney, Thomas F., University of Ill.
13702 Conrad, Clarence L., University of Illinois
13703 Groeger, Roscoe C., University of Illinois
13704 Gulley, Sanford J., University of Illinois
13705 Hornback, Robert H., University of Ill.
13706 Kerchner, Russell M., University of Ill.
13707 Kerns, Arthur D., University of Illinois
13708 Krause, Elmer G., University of Illinois
13709 Love, John J., University of Illinois
13710 Robinson, Clyde N., University of Illinois
13711 Schmalmaack, Charles L., Univ. of Ill.
13712 Shapiro, Leo, University of Illinois
13713 Smith, Charles C., University of Illinois
13714 Stenicka, Charles E., University of Illinois
13715 Vallier, Justin D., University of Illinois
13716 Breyfogel, Albert W., University of Ill.
13717 Hardcastle, Edward, Lehigh University
13718 Hoke, William M., Lehigh University
13719 Barber, Frederick E., Lehigh University
13720 Rieman, Edwin F., Lehigh University
13721 Picht, George C., Jr., Lehigh University
13722 Schifreen, Clement S., Lehigh University
13723 Snyder, Edwin H., Jr., Lehigh University
13724 Van Billiard, Lewis H., Lehigh University
13725 Werner, David T., Lehigh University
13726 Ferry, John F., Lehigh University
13727 Forney, Charles D., Lehigh University
13728 Hagenbuch, Edward A., Jr., Lehigh Univ.
13729 Henschen, Leroy, Lehigh University
13730 Knouse, Walter E., Lehigh University
13731 Maxwell, Thomas, Lehigh University
13732 Muzdakis, John R., Lehigh University
13733 Nichols, Robert W., Lehigh University
13734 Kressler, Charles H., Lehigh University
13735 Minnich, Joseph P., Lehigh University
13736 McPherson, John D., Jr., Lehigh Univ.
13737 Regad, Eugene D., Lehigh University
13738 Appel, Carl W., Lehigh University
13739 Blankenbuehler, John H., Lehigh Univ.
13740 Bishop, C. Fletcher, Lehigh University
13741 Derrick, Charles L., Lehigh University
13742 Ancona, Frederick B., Lehigh University
13743 Bodey, Carl F., Lehigh University
13744 Brotzman, Reginald P., Lehigh University
13745 Ferguson, Frank E., Jr., Lehigh University
13746 Burr, Harold K., Carnegie Institute of Tech.
13747 Feldmann, Merrick R., University of Colo.
13748 Seaman, Kermit G., University of Colo.
13749 Deibler, Orville M., Kansas State Agricultural College.
13750 Davidson, Cyrus C., Kansas State Agricultural College
13751 Cross, Paul C., Kansas State Agri. Coll.
13752 Frank, Karl C., Kansas State Agri. Coll.
13753 Geeslin, David M., Kansas State Agri. Coll.
13754 Williams, Howard, Kansas State Agri. Coll.
13755 Cook, Merriam E., Kansas State Agri. Coll.
13756 Birtles, William A., Toronto Central Technical School
13757 Heins, Rudolf J., University of Wisconsin
13758 Lanphier, Edward O., Sheffield Scientific School
13759 Williams, Charles A., Mass. Inst. of Tech.
13760 Moore, John B., Carnegie Inst. of Tech.
13761 Jennings, Lester E., Kansas State Agricultural College
13762 Pfundstein, Walter E., Kansas State Agricultural College
13763 Cox, Newton P., Lehigh University
13764 Wehrenberg, William, Jr., Lehigh Univ.
13765 Bryn, Harold B., University of Wisconsin
13766 Heim, Howard J., University of Nebraska
13767 Franklin, Frederick, Sheffield Scientic Sch.
13768 Erdman, Wilson, Montana State College
13769 Rivenes, Alf, Montana State College
13770 Woodring, Hubert E., Kansas State Agricultural College
13771 Akin, George B., University of Kentucky
13772 Baugh, J. Frank, University of Kentucky
13773 Baumgarten, George W., University of Ky.
13774 Belt, Newton O., University of Kentucky
13775 Bennett, R. M., University of Kentucky
13776 Craig, Raymond H., Univ. of Kentucky
13777 David, Harold T., University of Kentucky
13778 Fendley, S. D., University of Kentucky
13779 Futrell, William D., Univ. of Kentucky
13780 Gibbons, Clyde R., Univ. of Kentucky
13781 Gibson, Boen G., University of Kentucky
13782 Gregg, Samuel S., University of Kentucky
13783 Hayslett, Lamar E., University of Kentucky
13784 Holbrook, Yancy C., Univ. of Kentucky
13785 Kefauver, William G., Univ. of Kentucky
13786 Kelly, James R., Univ. of Kentucky
13787 Miller, William G., Univ. of Kentucky
13788 Nicholson, George K., Univ. of Kentucky
13789 Owens, Joseph W., University of Kentucky
13790 Propps, Thomas B., Univ. of Kentucky
13791 Riley, Thomas M., Univ. of Kentucky
13792 Roberts, Cary R., University of Kentucky
13793 Shanklin, Arthur P., Univ. of Kentucky
13794 Slomer, Joseph J., University of Kentucky
13795 Soper, Lawrence A., Jr., Univ. of Kentucky
13796 Stokes, William K., Univ. of Kentucky
13797 Thornton, David L., Univ. of Kentucky
13798 Walling, Harry W., University of Kentucky
13799 Wilkerson, Neil M., Univ. of Kentucky
13800 Witt, Norman D., University of Kentucky
13801 Woodward, Rothwell, Univ. of Kentucky
13802 Young, Chester C., University of Kentucky
13803 De Turk, Eli R. S., Bucknell University
13804 Schuele, Martin A., University of Arizona
13805 Macdonald, Ralph A., Univ. of Arizona
13806 Hedgepeth, William J., Univ. of Arizona
13807 Simonds, Cecil L., University of Arizona
13808 Spafford, Perry P., University of Arizona
13809 Mellen, J. A., University of Arizona
13810 Van Kirk, Russell W., Univ. of Arizona
13811 Hillman, Harry A., Jr., University of Ariz.
13812 Whitmore, Paul G., University of Arizona
13813 Hunt, Asa E., A. & M. College of Texas
13814 Price, Leslie D., Mass. Institute of Tech.
13815 Leibe, Frank A., Stevens Institute of Tech.
13816 Ware, Maximilian X., Univ. of Arkansas
13817 Barry, James C., Jr., Alabama Poly. Inst.
13818 Brownell, Harold S., Alabama Poly. Inst.
13819 Gillespie, Judson M., Alabama Poly. Inst.
13820 Hatchett, Benjamin F., Alabama Poly. Inst
13821 Johnson, Joseph T., Alabama Poly. Inst.
13822 Marsh, Bryan B., Alabama Poly. Inst.
13823 Purifoy, George R., Alabama Poly. Inst.
13824 Sampley, Roy C., Alabama Poly. Institute
13825 Sims, William B., Alabama Poly. Institute
13826 Scott, Ernest D., Alabama Polytechnic Inst.
13827 Timberlake, Phil S., Alabama Poly. Inst.
13828 Whitson, Maria R., Alabama Poly. Inst.
13829 McCartney, Chas. E., Alabama Poly. Inst.
13830 Allen, Richard W., Brown University
13831 Ammerman, John A., Bucknell University
13832 Bainton, Ernest L., Brown University
13833 Selleck, Harold G., Carnegie Inst. of Tech.
13834 Sealey, William C., Carnegie Inst. of Tech.
13835 Wittenberger, Harvey S., School of Engg. of Milwaukee
13836 Taylor, Julian S., School of Engg. of Milwaukee
13837 Moreau, Marcel J., Scholl of Engg. of Milwaukee
13838 Haines, George E., School of Engg. of Milwaukee
13839 Bowker, Edgar I., School of Engg. of Milwaukee
13840 Lindenberg, G. D., School of Engg. of Milwaukee
13841 Fritschel, Ewald P., School of Engg. of Milwaukee
13842 Brown, Philip J., Lafayette College
13843 Baker, Charles H., Mass. Institute of Tech.
13844 Kittredge, Francis I., Worcester Poly. Inst.
13845 Millison, Earl G., Lewis Institute
13846 Roesch, Robert E., Cornell University
13847 Lung, Shun Yeu, Cornell University
13848 Bladen, Arthur McK., Cornell University
13849 Foster, Dudley E., Cornell University
13850 Dicianni, Leo J., Cornell University
13851 Beatty, Henry McI., Cornell University
13852 Fein, Morris, Cornell University
13853 Koch, George S., Lehigh University
13854 Blackman, M. J., Alabama Poly. Institute
13855 Knapp, I. Walter, Ohio Northern Univ.
13856 Lehman, Donald G., University of Wis.
13857 Shed, Henry G., Mass. Institute of Tech.
13858 Schwartz, Leon, New York Electrical Sch.
13859 Herrick, Neal D., University of Wisconsin
13860 Roseberry, Donald K., Lafayette College
13861 Parks, John E., University of Illinois
13862 Dehr, William B., University of Illinois
13863 Atkinson, Earl W., University of Illinois
13864 O'Connor, Roger R., University of Illinois
13865 Wolff, Samuel, University of Illinois
13866 Phillips, Lloyd R., Tri-State College
13867 Gammal, Albert A., Worcester Poly. Inst.
13868 House, Edwin R., Univ. of Cincinnati
13869 Greene, Robert B., University of Okla.
13870 Shockley, Henry M., University of Toronto
13871 Morrison, Frank W., Univ. of Cincinnati
13872 Rahr, Frederick, A., Jr., Univ. of Wisconsin
13873 Hurd, Clinton T., Oregon Agri. College
13874 Goodison, Alfred M., Jr., Univ. of Michigan
13875 Jantzen, James W., Univ. of Michigan
13876 Younglove, George W., Univ. of Michigan
13877 Coates, James O., Univ. of Michigan
13878 Ziegler, Edward G., Univ. of Michigan
13879 Williams, Joseph E., University of Mich.
13880 Koetsier, Arend J., Univ. of Michigan
13881 Tucker, Wilmer H., Carnegie Inst. of Tech.
13882 Macalpine, William W., Carnegie Institute of Technology
13883 Heberlein, Arthur A., Brooklyn Poly. Inst.
13884 Ramsden, Clayton W., Univ. of Penna.
13885 Wilford, Edward B., University of Penna.
13886 Heidelbaugh, E. C., University of Penna.
13887 Lucas, Harry C., University of Penna.
13888 Williams, Thomas W., University of Penna.
13889 Bloecker, William E., University of Penna.
13890 Grosse, George E., University of Penna.
13891 Gallagher, Jacob B., University of Penna.
13892 Meyerhoff, Lester B., University of Penna.
13893 Chilcott, Edward R., Mass. Inst. of Tech.
13894 Hawley, George L., University of Kansas
13895 Cochran, George L., University of Kansas
13896 Albach, Henry J., University of Kansas
13897 Sandman, David, Worcester Poly. Inst.
13898 Harner, John E., Kansas State Agri. Coll.
13899 Clarke, Harold J., Carnegie Inst. of Tech.
13900 Taylor, Elbert W. A., University of Illinois
13901 Jenny, Paul L., Carnegie Institute of Tech.
13902 Shean, Perry R., University of Maine
13903 Shultz, Charles A., Newark Technical Coll.
13904 Graves, Herbert P., University of Toronto
13905 Kimball, Harry R., Mass. Institute of Tech.

14046 Nordwall, Glen, Univ. of Minnesota
14047 Olin, Henry A., University of Minnesota
14048 Enger, Arue, R., University of Minnesota
14049 Hawkins, Harvey C., Univ. of Minnesota
14050 Tanell, Robert H., University of Minnesota
14051 Hargraves, Robert A., Univ. of Minnesota
14052 Lundquist, John V., Univ. of Minnesota
14053 Mindrum, Arthur I., Univ. of Minnesota
14054 Friedman, Edwin A., Univ. of Minnesota
14055 Schottler, George J., Univ. of Minnesota
14056 Pause, Harold A., University of Minnesota
14057 McCullough, Robert T., Univ. of Minn.
14058 Lieberman, Henry, Univ. of Minnesota
14059 Fix, Frederick W., Jr., Cornell University

Total 374.

OFFICERS OF A. I. E. E. 1921-1922

A. I. E. E. COMMITTEES

GENERAL STANDING COMMITTEES

MEMBERSHIP COMMITTEE
E. H. Martindale, Chairman, Martindale Electric Co., Station G., Cleveland, O.
Vice-Chairmen:
R. L. Dodd, F. L. Kemp, John Salberg,
D. B. Fleming, J. E. Macdonald, M. E. Skinner,
R. B. Howland, George H. Middlemiss, J. L. Woodress,
W. N. Ryerson,
Chairmen of local Section membership committees.

HEADQUARTERS COMMITTEE
W. A. Del Mar, Chairman, Habirshaw Elec. Cable Co., Yonkers, N. Y.
F. L. Hutchinson, L. F. Morehouse.

LAW COMMITTEE
H. H. Barnes, Jr., Chairman, 120 Broadway, New York.
Frank R. Ewart, P. Junkersfeld, Charles A. Terry.
L. F. Morehouse.

PUBLIC POLICY COMMITTEE
H. W. Buck, Chairman, 49 Wall St., New York.
Gano Dunn, John W. Lieb, Calvert Townley.
C. E. Skinner.

COMMITTEE ON CODE OF PRINCIPLES OF PROFESSIONAL CONDUCT
C. A. Adams, Chairman, Harvard University, Cambridge, Mass.
A. H. Babcock, G. Faccioli, Schuyler Skaats Wheeler,
George F. Sever.

COMMITTEE ON SAFETY CODES
H. B. Gear, Chairman, 72 W. Adams St., Chicago, Ill.
H. C. Cushing, M. G. Lloyd, Farley Osgood,
J. C. Forsyth, Wills Maclachlan, H. R. Sargent,
H. O. Lacount, R. W. E. Moore, A. M. Schoen,
Johnston Livingston, H. N. Muller, H. S. Warren.

STANDARDS COMMITTEE
Harold Pender, Chairman, University of Pennsylvania, Philadelphia, Pa.
H. S. Osborne, Secretary, 195 Broadway, New York.
G. A. Anderegg, F. C. Hanker, L. F. Morehouse,
Frederick Bedell, Percy E. Hart, F. D. Newbury,
B. A. Behrend, H. M. Hobart, S. G. Rhodes,
O. B. Blackwell, Dugald C. Jackson, Charles Robbins,
L. F. Blume, P. Junkersfeld, L. T. Robinson,
G. A. Burnham, G. L. Knight, R. F. Schuchardt,
P. H. Chase, F. A. Laws, C. E. Skinner,
E. J. Cheney, C. O. Mailloux, Arthur B. Smith,
L. W. Chubb, C. S. McDowell, N. W. Storer,
F. P. Cox, W. L. Merrill, John B. Taylor,
E. B. Craft, J. F. Meyer, A. H. Timmerman,
W. A. Del Mar, Taliaferro Milton, Philip Torchio
F. M. Farmer, R. W. E. Moore, W. K. Vanderpoel,
H. W. Fisher, R. B. Williamson.

EDISON MEDAL COMMITTEE
Appointed by the President for term of five years.
(Term expires July 31, 1922)
Comfort A. Adams, Chairman,
L. A. Ferguson, S. W. Stratton.
(Term expires July 31, 1923.)
Frederick Bedell, L. T. Robinson, Calvert Townley,
(Term expires July 31, 1924.)
E. D. Adams, H. H. Barnes, Jr. B. G. Lamme.
(Term expires July 31, 1925.)
H. M. Byllesby, D. E. Drake, W. L. R. Emmet.
(Term expires July 31, 1926.)
B. A. Behrend, John H. Finney, C. S. Ruffner.
Elected by the Board of Directors from its own membership for term of two years
(Term expires July 31, 1922.)
L. E. Imlay, F. D. Newbury, W. I. Slichter.
(Term expires July 31, 1923.)
A. W. Berresford, L. F. Morehouse, R. B. Williamson.
Ex-Officio
Wm. McClellan, President. George A. Hamilton, Treasurer.
F. L. Hutchinson, Secretary.

RESEARCH COMMITTEE
F. B. Jewett, Chairman, 463 West St., New York, N. Y.
B. A. Behrend, Bancroft Gherardi, L. F. Morehouse,
Frederick Bedell, D. C. Jackson, E. W. Rice, Jr.
F. S. Clark, P. Junkersfeld, Clayton H. Sharp,
E. B. Craft, A. E. Kennelly, C. E. Skinner,
E. E. F. Creighton, John B. Klumpp, Elmer A. Sperry,
H. P. Davis, M. G. Lloyd, Schuyler Skaats Wheeler,
W. A. Del Mar, John B. Whitehead.

TECHNICAL COMMITTEES

EDUCATIONAL
C. E. Magnusson, Chairman, University of Washington, Seattle, Wash.
W. C. Bauer, Charles S. Howe, R. F. Schuchardt,
Edward Bennett, John C. Parker, W. L. Upson,
C. R. Dooley, G. H. Pfeif, Wm. R. Work.
H. W. Price,

ELECTRICAL MACHINERY
B. A. Behrend, Chairman, 85 Devonshire St., Boston, Mass.
A. S. McAllister, Secretary, 218 W. 76th St., New York,
B. L. Barns, V. A. Fynn, A. S. McAllister
R. E. Brown, David Hall, F. D. Newbury,
James Burke, H. U. Hart, Philip Torchio,
G. Faccioli, V. Karapetoff, Herman L. Wallau,
W. J. Foster, Paul Lincoln, R. B. Williamson.

ELECTROCHEMISTRY AND ELECTROMETALLURGY
Lawrence Addicks, Chairman, 51 Maiden Lane, New York,
F. G. Clark, Carl Hering, W. H. Powell,
I. R. Edmands, L. E. Imlay, J. A. Seede,
James J. Farley, F. A. Lidbury, J. L. Yardley.

ELECTROPHYSICS
F. W. Peek, Jr., Chairman, General Electric Co., Pittsfield, Mass.
H. D. Arnold, J. C. Clark, E. P. Hyde,
E. F. Burton, C. P. Eldred, Chester W. Rice,
L. W. Chubb, Charles Fortescue, H. B. Smith.
Roy S. Glasgow,

INDUSTRIAL AND DOMESTIC POWER
W. C. Yates, Chairman, General Electric Co., Schenectady, N. Y.
P. H. Adams, Charles D. Fawcett, A. C. Lanier,
H. W. Cope, C. T. Guildford, M. J. McHenry,
W. E. Date, Henry D. James, A. G. Pierce,
E. D. Doyle, Fraser Jeffrey, H. P. Reed,
C. W. Drake, W. C. Kalb, Leo Schirtzinger,
H. W. Eastwood, C. W. Kincaid Carl F. Scott.

INSTRUMENTS AND MEASUREMENTS
F. V. Magalhaes, Chairman, 55 Duane St., New York, N. Y.
C. W. Baker, F. P. Cox, G. A. Sawin,
P. A. Borden, E. D. Doyle H. B. Smith,
Wm. M. Bradshaw, A. L. Ellis, Irving B. Smith
H. B. Brooks, H. S. Vasser,

IRON AND STEEL INDUSTRY
E. S. Jefferies, Chairman, The Steel Co. of Canada Ltd., Hamilton, Ont.
F. B. Crosby, R. B. Gerhardt, G. E. Stoltz,
Gordon Fox, K. A. Pauly, Wilfred Skyes,
Eugene Friedlaender, D. M. Petty, F. H. Woodhull.
Wm. T. Snyder,

LIGHTING AND ILLUMINATION
G. H. Stickney, Chairman, Edison Lamp Works of G. E. Co., Harrison, N. J.
G. N. Chamberlin, W. T. Dempsey, Charles F. Scott,
A. B. Cooper, R. C. Powell, B. E. Shackelford,
J. R. Cravath, W. D'A. Ryan. W. M. Skiff,

MARINE
Arthur Parker, Chairman, N. Y. Shipbuilding Co., Camden, N. J.
L. C. Brooks, Secretary, Bethlehem Shipbuilding Corp., Quincy, Mass.
J. B. Bassett, Wm. Hetherington, Jr. I. H. Osborne,
R. A. Beekman, H. L. Hibbard, G. A. Pierce, Jr.,
Eskil Berg, J. S. Isdale S. M. Robinson
Maxwell W. Day, William F. James, H. M. Southgate,
David D. Faris, C. A. Jones, W. E. Thau,
E. G. Gallagher, C. S. McDowell E. P. Townsend,
H. Franklin Harvey, Jr. W. F. Meschenmoser, A. E. Waller,
F. W. Wood.

MINES
Graham Bright, Chairman, W. E. & M. Co., East Pittsburgh, Pa.
Willard C. Adams, L. C. Ilsley, W. F. Schwedes,
R. T. Andrae, G. M. Kennedy, F. L. Stone,
M. C. Benedict, R. L. Kingsland, W. A. Thomas,
H. W. Eales, A. B. Kiser, C. D. Woodward.

POWER STATIONS
H. A. Barre, H. W. Eales, F. D. Newbury,
J. T. Barron, F. C. Hanker, R. F. Schuchardt,
A. E. Bauhan, P. Junkersfeld, A. B. Stitzer,
E. T. Brandon, W. H. Lawrence, H. R. Summerhayes,
D. H. Braymer, H. P. Liversidge, R. B. Williamson.
I. E. Moultrop,

PROTECTIVE DEVICES
H. R. Woodrow, Chairman, Stone & Webster Corp., 147 Milk St., Boston, Mass.
G. H. Bragg, E. M. Hewlett, A. G. Pierce,
P. H. Chase, F. L. Hunt, N. L. Pollard,
W. H. Cole, J. B. MacNeill, F. E. Ricketts,
L. N. Crichton, John C. Martin, D. W. Roper,
F. C. Hanker, A. A. Meyer, E. R. Stauffacher,
S. E. M. Henderson, W. H. Millan, E. C. Stone,
E. A. Hester, John B. Taylor.

TELEGRAPHY AND TELEPHONY
Donald McNicol, Chairman, 132 Union Rd., Roselle Park, N. J.
O. B. Blackwell, C. E. Davies, W. O. Pennell,
C. W. Burkett, F. E. d'Humy, Stanley Rhoads,
G. A. Cellar, D. H. Gage, Edgar Russell,
R. E. Chetwood, H. Hulatt, A. E. Silver,
L. W. Chubb, F. H. Kroger, A. B. Smith,
E. H. Colpitts, L. F. Morehouse, F. A. Wolff.

TRACTION AND TRANSPORTATION
H. M. Brinckerhoff, Chairman, 84 Pine St., New York
A. H. Babcock, E. B. Katte, N. W. Storer,
Reinier Beeuwkes, John Murphy, R. W. Stovel,
R. H. Dalgleish, Hugh Pattison, H. M. Warren,
W. G. Gordon, W. B. Potter, F. E. Wynne,
Selby Haar, Ralph H. Rice, C. W. Young,
Guy A. Richardson.

TRANSMISSION AND DISTRIBUTION
Edward B. Meyer, Chairman, Public Service Electric Co., Newark, N. J.
R. W. Atkinson, John H. Finney, C. N. Rakestraw,
F. G. Baum, L. M. Klauber, C. C. Robinson,
Wallace S. Clark, J. A. Koontz, Jr., D. W. Roper,
W. H. Cole, W. S. Lee, C. H. Shaw,
W. A. Del Mar, G. J. Newton, A. E. Silver,
H. C. Don Carlos, A. M. Perry, W. K. Vanderpoel,
F. M. Farmer, C. T. Wilkinson.

A. I. E. E. REPRESENTATIVES

ON AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE, COUNCIL
F. B. Jewett, John B. Taylor.

ON AMERICAN BUREAU OF WELDING
W. L. Merrill.

ON AMERICAN COMMITTEE ON ELECTROLYSIS
Bion J. Arnold, N. A. Carle, F. N. Waterman.

ON AMERICAN ENGINEERING COUNCIL OF THE FEDERATED AMERICAN ENGINEERING SOCIETIES
Comfort A. Adams, W. A. Layman, Charles S. Ruffner,
A. W. Berresford, *William McClellan, *Charles F. Scott,
John H. Finney, L. F. Morehouse, *L. B. Stillwell,
F. L. Hutchinson, L. T. Robinson, *Calvert Townley.
*Members of Executive Board.

ON AMERICAN ENGINEERING STANDARDS COMMITTEE
Comfort A. Adams, H. M. Hobart, C. E. Skinner,
L. T. Robinson (Alternate)

ON BOARD OF TRUSTEES, UNITED ENGINEERING SOCIETY
H. H. Barnes, Jr., Bancroft Gherardi, H. A. Lardner.

ON ENGINEERING FOUNDATION BOARD
Frank B. Jewett, E. W. Rice, Jr.

ON FRANCO-AMERICAN ENGINEERING COMMITTEE
A. M. Hunt, L. B. Stillwell.

ON JOHN FRITZ MEDAL BOARD OF AWARD

Comfort A. Adams, A. W. Berresford, Calvert Townley, E. W. Rice, Jr.

ON LIBRARY BOARD OF UNITED ENGINEERING SOCIETY

Edward D. Adams, F. L. Hutchinson, Alfred W. Kiddle, E. B. Craft, W. I. Slichter.

ON NATIONAL FIRE PROTECTION ASSOCIATION, ELECTRICAL COMMITTEE

The chairman of the Institute's Committee on Safety Codes.

ON NATIONAL RESEARCH COUNCIL, ENGINEERING DIVISION

C. A. Adams, Frank B. Jewett, W. R. Whitney.

ON U. S. NATIONAL COMMITTEE OF THE INTERNATIONAL ILLUMINATION COMMISSION

A. E. Kennelly, C. O. Mailloux, Clayton H. Sharp.

WASHINGTON AWARD, COMMISSION OF

John Price Jackson, Charles F. Scott.

U. S. NATIONAL COMMITTEE OF THE INTERNATIONAL ELECTROTECHNICAL COMMISSION

C. O. Mailloux, President, 111 Fifth Ave., New York, N. Y.
D. C. Jackson, Vice-President,
*James Burke, Vice-President,
C. H. Sharp, Secretary, 556 E. 80th St., New York.

C. A. Adams,	W. C. Fish,	L. T. Robinson,
P. G. Agnew,	H. W. Fisher,	Charles Robbins,
B. A. Behrend,	H. M. Hobart,	D. B. Rushmore,
J. J. Carty,	A. E. Kennelly,	C. F. Scott,
L. W. Chubb,	B. G. Lamme,	C. E. Skinner,
*C. L. Collens, 2d,	A. S. McAllister,	S. W. Stratton,
W. A. Del Mar,	W. S. Moody,	Elihu Thomson,
*A. L. Doremus,	A. H. Moore,	†C. L. Warwick,
Gano Dunn,	R. W. E. Moore,	R. B. Williamson.
	L. F. Morehouse,	

*Representative of Electric Power Club.
†Representative of American Society for Testing Materials.

LIST OF SECTIONS

Name	Chairman	Secretary
Akron	H. C. Stephens	R. B. Fisher, 84 Rhodes Ave., Akron, O.
Atlanta	J. E. Mellett	H. N. Pye, Box 1743, Atlanta, Ga.
Baltimore	Douglas Burnett	Vern E. Alden, 1905 Lexington Building, Baltimore, Md.
Boston	Lewis W. Abbott	F. S. Dellenbaugh, M. I. T., Cambridge, Mass.
Chicago	M. M. Fowler	E. H. Bangs, 212 W. Washington St., Chicago, Ill.
Cincinnati	J. D. Lyon	Leo Schirtzinger, 710 Traction Bldg., Cincinnati, O.
Cleveland	I. H. Van Horn	G. B. Schneeberger, Cleveland Elec. Illuminating Co., Cleveland, O.
Connecticut	C. F. Scott	A. E. Knowlton, Dunham Laboratory, Yale University, New Haven, Conn.
Denver	B. C. J. Wheatlake	R. B. Bonney, 603 Wyoming Bldg., Denver, Colo.
Detroit-Ann Arbor	A. S. Albright	E. L. Bailey, 707 Ford Bldg., Detroit, Mich.
Erie	C. H. Schum	P. B. Mansfield, Lawrence Park, Erie, Pa.
Fort Wayne	R. H. Chadwick	A. B. Campbell, General Electric Co., Ft. Wayne, Ind.
Indianapolis-Lafayette	J. Lloyd Wayne	D. C. Pyke, Public Service Com. State House, Indianapolis, Ind.
Ithaca	J. G. Pertsch, Jr.	G. F. Bason, Cornell University, Ithaca, N. Y.
Kansas City	G. C. Shaad	J. W. Wopat, 822 K. C. Tel. Bldg., Kansas City, Mo.
Lehigh Valley	Charles Hodge	H. G. Harvey, Penna. Utilities Co., Easton, Pa.
Los Angeles	Herbert H. Cox	J. N. Kelman, 1650 Naud St., Los Angeles, Cal.
Lynn	F. J. Rudd	D. F. Smalley, General Electric Co., West Lynn, Mass.
Madison	C. B. Hayden	H. M. Crothers, Univ. of Wisconsin, Madison, Wis.
Milwaukee	F. J. Mayer	P. B. Harwood, Cutler-Hammer Mfg. Co., Milwaukee, Wis.
Minnesota	W. T. Ryan	F. A. Otto, 639 Holly Ave., St. Paul, Minn.
New York	Farley Osgood	H. A. Pratt, 165 Broadway, New York, N. Y.
Panama	R. D. Prescott	M. P. Benninger, Box 174, Balboa Heights, C. Z.
Philadelphia	P. H. Chase	R. B. Mateer, Phila. Elec. Co., 1000 Chestnut St., Philadelphia, Pa.
Pittsburgh	H. W. Smith	E. C. Stone, Duquesne Light Co., 435 6th Ave., Pittsburgh, Pa.
Pittsfield	I. H. Sclater	A. C. Stevens, General Electric Co., Pittsfield, Mass.
Portland, Ore.	W. C. Heston	D. W. Proebstel, Portland Ry. Lt. & Pr. Co., Portland, Ore.
Providence	Nicholas Stahl	F. N. Tompkins, Brown Univ., Providence, R. I.
Rochester	Sidney Alling	A. M. Stetler, Aluminum Co. of America, Granite Bldg., Rochester, N. Y.
St. Louis	J. L. Woodress	W. H. Millan, Union Elec. Lt. & Pr. Co., St. Louis, Mo.
San Francisco	W. P. L'Hommedieu	A. G. Jones, 809 Rialto Bldg., San Francisco, Cal.
Schenectady	S. H. Blake	C. W. Fick, General Electric Co., Schenectady, N. Y.
Seattle	J. P. Growdon	E. S. Code, 1400 Alaska Bldg., Seattle, Wash.
Spokane	L. J. Pospisil	H. L. Melvin, Washington Water Power Co., Spokane, Wash.
Syracuse	E. T. Moore	Elmer E. Strong, 614 City Bank Bldg., Syracuse, N. Y.
Toledo		Max Neuber, 1257 Fernwood Ave., Toledo, O.
Toronto	W. P. Dobson	P. A. Borden, 8 Strachan Ave., Toronto, Ont.
Urbana	E. H. Waldo	H. A. Brown, Univ. of Illinois, Urbana, Ill.
Utah	P. P. Ashworth	C. R. Higson, Utah Power & Light Co., Salt Lake City, Utah
Vancouver	John R. Read	F. W. McNeill, Canadian General Elec. Co., Vancouver, B.C.
Washington, D. C.	A. R. Cheyney	W. A. E. Doying, Panama Canal Commission, Washington, D.C.
Worcester	G. M. Hardy	Dean J. Locke, 125 Salisbury St., Worcester, Mass.

Total 42

LIST OF BRANCHES

Name and Location	Chairman	Secretary
Alabama Poly. Inst., Auburn, Ala.	V. C. McIlvaine	J. M. Dickinson
Alabama, Univ. of, University, Ala.	D. H. Davis	W. W. Bauder
Arkansas, Univ. of, Fayetteville, Ark.	M. X. Ware	B. R. Askew
Armour Inst. of Tech., Chicago, Ill.	R. P. Burns	L. E. Grube
Brooklyn Poly. Inst., Brooklyn, N. Y.	H. Ladner	O. Engstrom
Bucknell Univ., Lewisburg, Pa.	F. T. Tingley	J. A. Ammerman
California Inst. of Tech., Pasadena, Cal.	O. R. Bulkley	L. J. Wells
California, Univ. of, Berkeley, Cal.	W. E. Newton	E. F. McNaughton
Carnegie Inst. of Tech., Pittsburgh, Pa.	E. A. Brand	H. W. Bryan
Case School of Applied Science, Cleveland, O.	M. A. Hyde, Jr.	O. Henderson
Cincinnati, Univ. of, Cincinnati, O.	J. R. Petree	C. B. Hoffmann
Clarkson Coll. of Tech., Potsdam, N.Y.	R. L. Conboy	F. H. Fults
Clemson Agri. College, Clemson College, S. C.	J. R. Reardon	J. R. Rosa
Colorado, Univ. of, Boulder, Colo.	T. D. Sylvester	F. B. Doolittle
Drexel Institute, Philadelphia, Pa.	G. J. Davis	C. F. Peterson
Georgia School of Tech., Atlanta, Ga.	C. D. LeBey	E. V. Wallace
